

# EFM8 Busy Bee Family

## EFM8BB1 Reference Manual

The EFM8BB1, part of the Busy Bee family of MCUs, is a multi-purpose line of 8-bit microcontrollers with a comprehensive feature set in small packages.

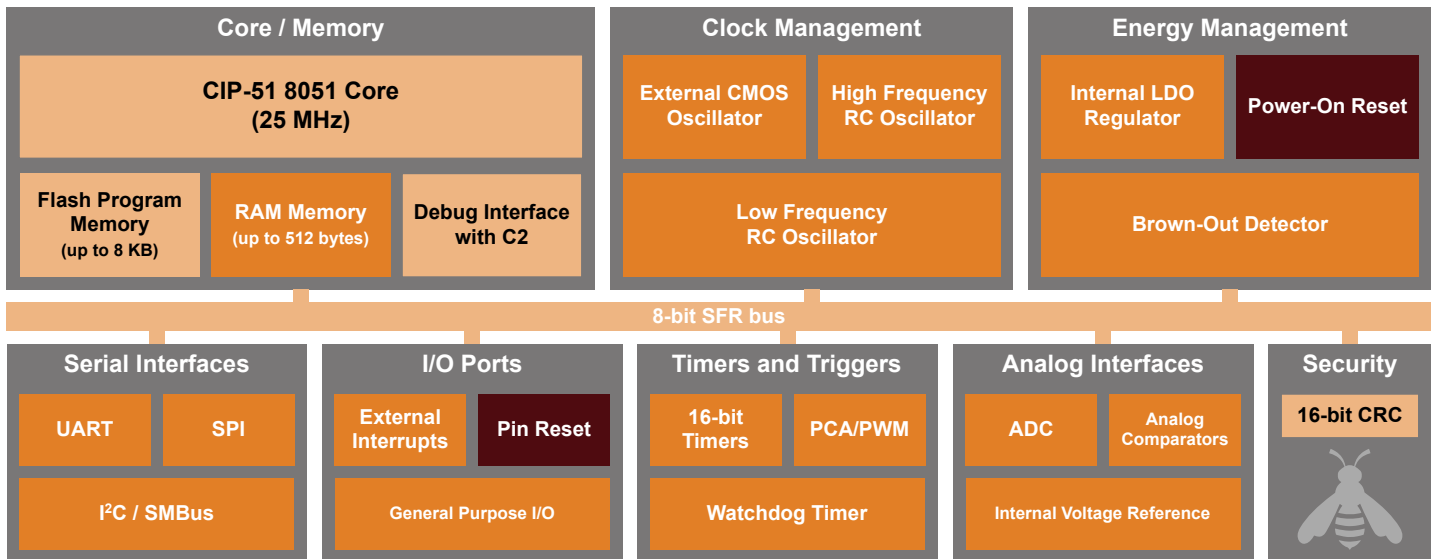

These devices offer high-value by integrating advanced analog and communication peripherals into small packages, making them ideal for space-constrained applications. With an efficient 8051 core, enhanced pulse-width modulation, and precision analog, the EFM8BB1 family is also optimal for embedded applications.

EFM8BB1 applications include the following:

- Motor control
- Consumer electronics
- Sensor controllers
- Medical equipment
- Lighting systems
- I/O port expander

### KEY FEATURES

- Pipelined 8-bit C8051 core with 25 MHz maximum operating frequency
- Up to 18 multifunction, 5 V tolerant I/O pins
- One 12-bit Analog to Digital converter (ADC)
- Two low-current analog comparators
- Integrated temperature sensor
- 3-channel enhanced PWM / PCA
- Four 16-bit timers
- UART, SPI and SMBus/I2C
- Priority crossbar for flexible pin mapping

Lowest power mode with peripheral operational:

- Normal
- Idle
- Shutdown

# 1. System Overview

## 1.1 Introduction

Figure 1.1. Detailed EFM8BB1 Block Diagram

## 1.2 Power

All internal circuitry draws power from the VDD supply pin. External I/O pins are powered from the VIO supply voltage (or VDD on devices without a separate VIO connection), while most of the internal circuitry is supplied by an on-chip LDO regulator. Control over the device power can be achieved by enabling/disabling individual peripherals as needed. Each analog peripheral can be disabled when not in use and placed in low power mode. Digital peripherals, such as timers and serial buses, have their clocks gated off and draw little power when they are not in use.

**Table 1.1. Power Modes**

Power Mode	Details	Mode Entry	Wake-Up Sources
Normal	Core and all peripherals clocked and fully operational	—	—
Idle	<ul style="list-style-type: none"> <li>Core halted</li> <li>All peripherals clocked and fully operational</li> <li>Code resumes execution on wake event</li> </ul>	Set IDLE bit in PCON0	Any interrupt
Shutdown	<ul style="list-style-type: none"> <li>All internal power nets shut down</li> <li>Pins retain state</li> <li>Exit on pin or power-on reset</li> </ul>	<ol style="list-style-type: none"> <li>Set STOPCF bit in REG0CN</li> <li>Set STOP bit in PCON0</li> </ol>	<ul style="list-style-type: none"> <li>RSTb pin reset</li> <li>Power-on reset</li> </ul>

## 1.3 I/O

Digital and analog resources are externally available on the device's multi-purpose I/O pins. Port pins P0.0-P1.7 can be defined as general-purpose I/O (GPIO), assigned to one of the internal digital resources through the crossbar or dedicated channels, or assigned to an analog function. Port pins P2.0 and P2.1 can be used as GPIO. Additionally, the C2 Interface Data signal (C2D) is shared with P2.0.

- Up to 18 multi-functions I/O pins, supporting digital and analog functions.
- Flexible priority crossbar decoder for digital peripheral assignment.
- Two drive strength settings for each port.
- Two direct-pin interrupt sources with dedicated interrupt vectors (INT0 and INT1).
- Up to 16 direct-pin interrupt sources with shared interrupt vector (Port Match).

## 1.4 Clocking

The CPU core and peripheral subsystem may be clocked by both internal and external oscillator resources. By default, the system clock comes up running from the 24.5 MHz oscillator divided by 8.

- Provides clock to core and peripherals.
- 24.5 MHz internal oscillator (HFOSC0), accurate to  $\pm 2\%$  over supply and temperature corners.
- 80 kHz low-frequency oscillator (LFOSC0).
- External CMOS clock input (EXTCLK).
- Clock divider with eight settings for flexible clock scaling: Divide the selected clock source by 1, 2, 4, 8, 16, 32, 64, or 128.

## 1.5 Counters/Timers and PWM

### Programmable Counter Array (PCA0)

The programmable counter array (PCA) provides multiple channels of enhanced timer and PWM functionality while requiring less CPU intervention than standard counter/timers. The PCA consists of a dedicated 16-bit counter/timer and one 16-bit capture/compare module for each channel. The counter/timer is driven by a programmable timebase that has flexible external and internal clocking options. Each capture/compare module may be configured to operate independently in one of five modes: Edge-Triggered Capture, Software Timer, High-Speed Output, Frequency Output, or Pulse-Width Modulated (PWM) Output. Each capture/compare module has its own associated I/O line (CEXn) which is routed through the crossbar to port I/O when enabled.

- 16-bit time base
- Programmable clock divisor and clock source selection
- Up to three independently-configurable channels
- 8, 9, 10, 11 and 16-bit PWM modes (center or edge-aligned operation)
- Output polarity control
- Frequency output mode
- Capture on rising, falling or any edge
- Compare function for arbitrary waveform generation
- Software timer (internal compare) mode
- Can accept hardware “kill” signal from comparator 0

### Timers (Timer 0, Timer 1, Timer 2, and Timer 3)

Several counter/timers are included in the device: two are 16-bit counter/timers compatible with those found in the standard 8051, and the rest are 16-bit auto-reload timers for timing peripherals or for general purpose use. These timers can be used to measure time intervals, count external events and generate periodic interrupt requests. Timer 0 and Timer 1 are nearly identical and have four primary modes of operation. The other timers offer both 16-bit and split 8-bit timer functionality with auto-reload and capture capabilities.

Timer 0 and Timer 1 include the following features:

- Standard 8051 timers, supporting backwards-compatibility with firmware and hardware.
- Clock sources include SYSCLK, SYSCLK divided by 12, 4, or 48, the External Clock divided by 8, or an external pin.
- 8-bit auto-reload counter/timer mode
- 13-bit counter/timer mode
- 16-bit counter/timer mode
- Dual 8-bit counter/timer mode (Timer 0)

Timer 2 and Timer 3 are 16-bit timers including the following features:

- Clock sources include SYSCLK, SYSCLK divided by 12, or the External Clock divided by 8.
- 16-bit auto-reload timer mode
- Dual 8-bit auto-reload timer mode
- External pin capture (Timer 2)
- LFOSC0 capture (Timer 3)

### Watchdog Timer (WDT0)

The device includes a programmable watchdog timer (WDT) running off the low-frequency oscillator. A WDT overflow forces the MCU into the reset state. To prevent the reset, the WDT must be restarted by application software before overflow. If the system experiences a software or hardware malfunction preventing the software from restarting the WDT, the WDT overflows and causes a reset. Following a reset, the WDT is automatically enabled and running with the default maximum time interval. If needed, the WDT can be disabled by system software or locked on to prevent accidental disabling. Once locked, the WDT cannot be disabled until the next system reset. The state of the RST pin is unaffected by this reset.

The Watchdog Timer has the following features:

- Programmable timeout interval
- Runs from the low-frequency oscillator
- Lock-out feature to prevent any modification until a system reset

## 1.6 Communications and Other Digital Peripherals

### Universal Asynchronous Receiver/Transmitter (UART0)

UART0 is an asynchronous, full duplex serial port offering modes 1 and 3 of the standard 8051 UART. Enhanced baud rate support allows a wide range of clock sources to generate standard baud rates. Received data buffering allows UART0 to start reception of a second incoming data byte before software has finished reading the previous data byte.

The UART module provides the following features:

- Asynchronous transmissions and receptions
- Baud rates up to  $\text{SYSCLK}/2$  (transmit) or  $\text{SYSCLK}/8$  (receive)
- 8- or 9-bit data
- Automatic start and stop generation

### Serial Peripheral Interface (SPI0)

The serial peripheral interface (SPI) module provides access to a flexible, full-duplex synchronous serial bus. The SPI can operate as a master or slave device in both 3-wire or 4-wire modes, and supports multiple masters and slaves on a single SPI bus. The slave-select (NSS) signal can be configured as an input to select the SPI in slave mode, or to disable master mode operation in a multi-master environment, avoiding contention on the SPI bus when more than one master attempts simultaneous data transfers. NSS can also be configured as a firmware-controlled chip-select output in master mode, or disabled to reduce the number of pins required. Additional general purpose port I/O pins can be used to select multiple slave devices in master mode.

The SPI module includes the following features:

- Supports 3- or 4-wire operation in master or slave modes.
- Supports external clock frequencies up to  $\text{SYSCLK} / 2$  in master mode and  $\text{SYSCLK} / 10$  in slave mode.
- Support for four clock phase and polarity options.
- 8-bit dedicated clock rate generator.
- Support for multiple masters on the same data lines.

### System Management Bus / I2C (SMB0)

The SMBus I/O interface is a two-wire, bi-directional serial bus. The SMBus is compliant with the System Management Bus Specification, version 1.1, and compatible with the I<sup>2</sup>C serial bus.

The SMBus module includes the following features:

- Standard (up to 100 kbps) and Fast (400 kbps) transfer speeds.
- Support for master, slave, and multi-master modes.
- Hardware synchronization and arbitration for multi-master mode.
- Clock low extending (clock stretching) to interface with faster masters.
- Hardware support for 7-bit slave and general call address recognition.
- Firmware support for 10-bit slave address decoding.
- Ability to inhibit all slave states.
- Programmable data setup/hold times.

### 16-bit CRC (CRC0)

The cyclic redundancy check (CRC) module performs a CRC using a 16-bit polynomial. CRC0 accepts a stream of 8-bit data and posts the 16-bit result to an internal register. In addition to using the CRC block for data manipulation, hardware can automatically CRC the flash contents of the device.

The CRC module is designed to provide hardware calculations for flash memory verification and communications protocols. The CRC module supports the standard CCITT-16 16-bit polynomial (0x1021), and includes the following features:

- Support for CCITT-16 polynomial
- Byte-level bit reversal
- Automatic CRC of flash contents on one or more 256-byte blocks
- Initial seed selection of 0x0000 or 0xFFFF

## 1.7 Analog

### 12-Bit Analog-to-Digital Converter (ADC0)

The ADC is a successive-approximation-register (SAR) ADC with 12-, 10-, and 8-bit modes, integrated track-and hold and a programmable window detector. The ADC is fully configurable under software control via several registers. The ADC may be configured to measure different signals using the analog multiplexer. The voltage reference for the ADC is selectable between internal and external reference sources.

- Up to 16 external inputs.
- Single-ended 12-bit and 10-bit modes.
- Supports an output update rate of 200 ksps samples per second in 12-bit mode or 800 ksps samples per second in 10-bit mode.
- Operation in low power modes at lower conversion speeds.
- Asynchronous hardware conversion trigger, selectable between software, external I/O and internal timer sources.
- Output data window comparator allows automatic range checking.
- Support for burst mode, which produces one set of accumulated data per conversion-start trigger with programmable power-on settling and tracking time.
- Conversion complete and window compare interrupts supported.
- Flexible output data formatting.
- Includes an internal fast-settling reference with two levels (1.65 V and 2.4 V) and support for external reference and signal ground.
- Integrated temperature sensor.

### Low Current Comparators (CMP0, CMP1)

Analog comparators are used to compare the voltage of two analog inputs, with a digital output indicating which input voltage is higher. External input connections to device I/O pins and internal connections are available through separate multiplexers on the positive and negative inputs. Hysteresis, response time, and current consumption may be programmed to suit the specific needs of the application.

The comparator module includes the following features:

- Up to 8 external positive inputs.
- Up to 8 external negative inputs.
- Additional input options:
  - Internal connection to LDO output.
  - Direct connection to GND.
- Synchronous and asynchronous outputs can be routed to pins via crossbar.
- Programmable hysteresis between 0 and  $\pm 20$  mV
- Programmable response time.
- Interrupts generated on rising, falling, or both edges.

## 1.8 Reset Sources

Reset circuitry allows the controller to be easily placed in a predefined default condition. On entry to this reset state, the following occur:

- The core halts program execution.
- Module registers are initialized to their defined reset values unless the bits reset only with a power-on reset.
- External port pins are forced to a known state.
- Interrupts and timers are disabled.

All registers are reset to the predefined values noted in the register descriptions unless the bits only reset with a power-on reset. The contents of RAM are unaffected during a reset; any previously stored data is preserved as long as power is not lost. The Port I/O latches are reset to 1 in open-drain mode. Weak pullups are enabled during and after the reset. For Supply Monitor and power-on resets, the RSTb pin is driven low until the device exits the reset state. On exit from the reset state, the program counter (PC) is reset, and the system clock defaults to an internal oscillator. The Watchdog Timer is enabled, and program execution begins at location 0x0000.

Reset sources on the device include the following:

- Power-on reset
- External reset pin
- Comparator reset
- Software-triggered reset
- Supply monitor reset (monitors VDD supply)
- Watchdog timer reset
- Missing clock detector reset
- Flash error reset

## 1.9 Debugging

The EFM8BB1 devices include an on-chip Silicon Labs 2-Wire (C2) debug interface to allow flash programming and in-system debugging with the production part installed in the end application. The C2 interface uses a clock signal (C2CK) and a bi-directional C2 data signal (C2D) to transfer information between the device and a host system. See the C2 Interface Specification for details on the C2 protocol.

## 1.10 Bootloader

All devices come pre-programmed with a UART bootloader. This bootloader resides in flash and can be erased if it is not needed.

## 2. Memory Organization

### 2.1 Memory Organization

The memory organization of the CIP-51 System Controller is similar to that of a standard 8051. There are two separate memory spaces: program memory and data memory. Program and data memory share the same address space but are accessed via different instruction types. Program memory consists of a non-volatile storage area that may be used for either program code or non-volatile data storage. The data memory, consisting of "internal" and "external" data space, is implemented as RAM, and may be used only for data storage. Program execution is not supported from the data memory space.

### 2.2 Program Memory

The CIP-51 core has a 64 KB program memory space. The product family implements some of this program memory space as in-system, re-programmable flash memory. Flash security is implemented by a user-programmable location in the flash block and provides read, write, and erase protection. All addresses not specified in the device memory map are reserved and may not be used for code or data storage.

### MOVX Instruction and Program Memory

The MOVX instruction in an 8051 device is typically used to access external data memory. On the devices, the MOVX instruction is normally used to read and write on-chip XRAM, but can be re-configured to write and erase on-chip flash memory space. MOVC instructions are always used to read flash memory, while MOVX write instructions are used to erase and write flash. This flash access feature provides a mechanism for the product to update program code and use the program memory space for non-volatile data storage.

### 2.3 Data Memory

The RAM space on the chip includes both an "internal" RAM area which is accessed with MOV instructions, and an on-chip "external" RAM area which is accessed using MOVX instructions. Total RAM varies, based on the specific device. The device memory map has more details about the specific amount of RAM available in each area for the different device variants.

#### Internal RAM

There are 256 bytes of internal RAM mapped into the data memory space from 0x00 through 0xFF. The lower 128 bytes of data memory are used for general purpose registers and scratch pad memory. Either direct or indirect addressing may be used to access the lower 128 bytes of data memory. Locations 0x00 through 0x1F are addressable as four banks of general purpose registers, each bank consisting of eight byte-wide registers. The next 16 bytes, locations 0x20 through 0x2F, may either be addressed as bytes or as 128 bit locations accessible with the direct addressing mode.

The upper 128 bytes of data memory are accessible only by indirect addressing. This region occupies the same address space as the Special Function Registers (SFR) but is physically separate from the SFR space. The addressing mode used by an instruction when accessing locations above 0x7F determines whether the CPU accesses the upper 128 bytes of data memory space or the SFRs. Instructions that use direct addressing will access the SFR space. Instructions using indirect addressing above 0x7F access the upper 128 bytes of data memory.

#### General Purpose Registers

The lower 32 bytes of data memory, locations 0x00 through 0x1F, may be addressed as four banks of general-purpose registers. Each bank consists of eight byte-wide registers designated R0 through R7. Only one of these banks may be enabled at a time. Two bits in the program status word (PSW) register, RS0 and RS1, select the active register bank. This allows fast context switching when entering subroutines and interrupt service routines. Indirect addressing modes use registers R0 and R1 as index registers.

## Bit Addressable Locations

In addition to direct access to data memory organized as bytes, the sixteen data memory locations at 0x20 through 0x2F are also accessible as 128 individually addressable bits. Each bit has a bit address from 0x00 to 0x7F. Bit 0 of the byte at 0x20 has bit address 0x00 while bit 7 of the byte at 0x20 has bit address 0x07. Bit 7 of the byte at 0x2F has bit address 0x7F. A bit access is distinguished from a full byte access by the type of instruction used (bit source or destination operands as opposed to a byte source or destination).

The MCS-51™ assembly language allows an alternate notation for bit addressing of the form XX.B where XX is the byte address and B is the bit position within the byte. For example, the instruction:

```
Mov C, 22.3h
```

moves the Boolean value at 0x13 (bit 3 of the byte at location 0x22) into the Carry flag.

## Stack

A programmer's stack can be located anywhere in the 256-byte data memory. The stack area is designated using the Stack Pointer (SP) SFR. The SP will point to the last location used. The next value pushed on the stack is placed at SP+1 and then SP is incremented. A reset initializes the stack pointer to location 0x07. Therefore, the first value pushed on the stack is placed at location 0x08, which is also the first register (R0) of register bank 1. Thus, if more than one register bank is to be used, the SP should be initialized to a location in the data memory not being used for data storage. The stack depth can extend up to 256 bytes.

## External RAM

On devices with more than 256 bytes of on-chip RAM, the additional RAM is mapped into the external data memory space (XRAM). Addresses in XRAM area accessed using the external move (MOVX) instructions.

**Note:** The 16-bit MOVX write instruction is also used for writing and erasing the flash memory. More details may be found in the flash memory section.

**Figure 2.5. XRAM Memory**

## 3. Special Function Registers

### 3.1 Special Function Register Access

The direct-access data memory locations from 0x80 to 0xFF constitute the special function registers (SFRs). The SFRs provide control and data exchange with the CIP-51's resources and peripherals. The CIP-51 duplicates the SFRs found in a typical 8051 implementation as well as implementing additional SFRs used to configure and access the sub-systems unique to the MCU. This allows the addition of new functionality while retaining compatibility with the MCS-51™ instruction set.

The SFR registers are accessed anytime the direct addressing mode is used to access memory locations from 0x80 to 0xFF. SFRs with addresses ending in 0x0 or 0x8 (e.g., P0, TCON, SCON0, IE, etc.) are bit-addressable as well as byte-addressable. All other SFRs are byte-addressable only. Unoccupied addresses in the SFR space are reserved for future use. Accessing these areas will have an indeterminate effect and should be avoided.

## 4. Flash Memory

### 4.1 Introduction

On-chip, re-programmable flash memory is included for program code and non-volatile data storage. The flash memory is organized in 512-byte pages. It can be erased and written through the C2 interface or from firmware by overloading the MOVX instruction. Any individual byte in flash memory must only be written once between page erase operations.

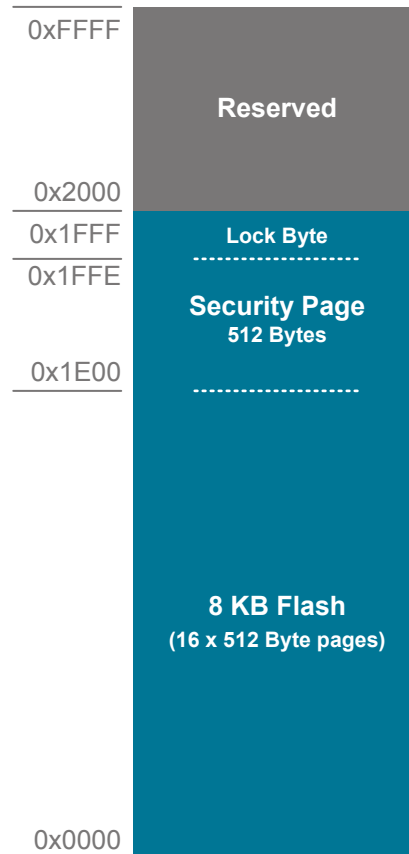

Figure 4.1. Flash Memory Map — 8 KB Devices

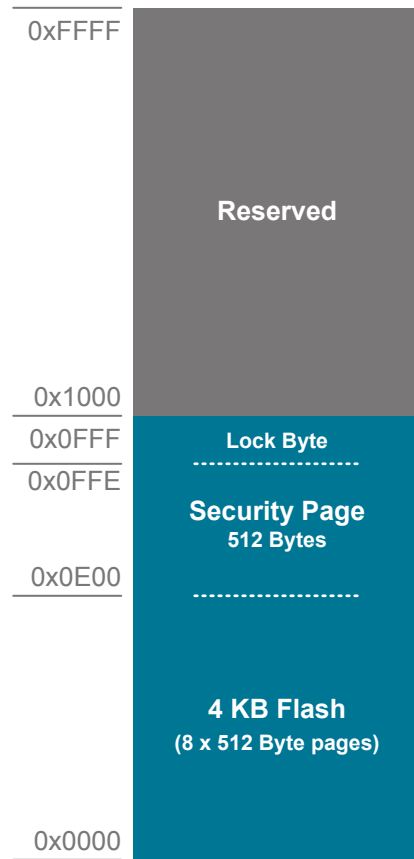

Figure 4.2. Flash Memory Map — 4 KB Devices

**Figure 4.3. Flash Memory Map — 2 KB Devices**

## 4.2 Features

The flash memory has the following features:

- Up to 8 KB organized in 512-byte sectors.
- In-system programmable from user firmware.
- Security lock to prevent unwanted read/write/erase access.

## 4.3 Functional Description

### 4.3.1 Security Options

The CIP-51 provides security options to protect the flash memory from inadvertent modification by software as well as to prevent the viewing of proprietary program code and constants. The Program Store Write Enable (bit PSWE in register PSCTL) and the Program Store Erase Enable (bit PSEE in register PSCTL) bits protect the flash memory from accidental modification by software. PSWE must be explicitly set to 1 before software can modify the flash memory; both PSWE and PSEE must be set to 1 before software can erase flash memory. Additional security features prevent proprietary program code and data constants from being read or altered across the C2 interface.

A Security Lock Byte located in flash user space offers protection of the flash program memory from access (reads, writes, or erases) by unprotected code or the C2 interface. See the specific device memory map for the location of the security byte. The flash security mechanism allows the user to lock "n" flash pages, starting at page 0, where "n" is the 1s complement number represented by the Security Lock Byte.

**Note:** The page containing the flash Security Lock Byte is unlocked when no other flash pages are locked (all bits of the Lock Byte are 1) and locked when any other flash pages are locked (any bit of the Lock Byte is 0).

**Table 4.1. Security Byte Decoding**

Security Lock Byte	111111101b
1s Complement	0000010b
Flash Pages Locked	3 (First two flash pages + Lock Byte Page)

The level of flash security depends on the flash access method. The three flash access methods that can be restricted are reads, writes, and erases from the C2 debug interface, user firmware executing on unlocked pages, and user firmware executing on locked pages.

**Table 4.2. Flash Security Summary—Firmware Permissions**

Target Area for Read / Write / Erase	Permissions according to the area firmware is executing from:			
	Unlocked User Page	Locked User Page	Unlocked Data Page	Locked Data Page
Any Unlocked Page	[R] [W] [E]	[R] [W] [E]	[R] [W] [E]	[R] [W] [E]
Locked Page (except security page)	reset	[R] [W] [E]	reset	[R] [W] [E]
Locked Security Page	reset	[R] [W]	reset	[R] [W]
Reserved Area	reset	reset	reset	reset
[R] = Read permitted [W] = Write permitted [E] = Erase permitted reset = Flash error reset triggered n/a = Not applicable				

**Table 4.3. Flash Security Summary—C2 Permissions**

Target Area for Read / Write / Erase	Permissions from C2 interface
Any Unlocked Page	[R] [W] [E]
Any Locked Page	Device Erase Only
Reserved Area	None

Target Area for Read / Write / Erase	Permissions from C2 interface
[R] = Read permitted	
[W] = Write permitted	
[E] = Erase permitted	
Device Erase Only = No read, write, or individual page erase is allowed. Must erase entire flash space.	
None = Read, write and erase are not permitted	

### 4.3.2 Programming the Flash Memory

Writes to flash memory clear bits from logic 1 to logic 0 and can be performed on single byte locations. Flash erasures set bits back to logic 1 and occur only on full pages. The write and erase operations are automatically timed by hardware for proper execution; data polling to determine the end of the write/erase operation is not required. Code execution is stalled during a flash write/erase operation.

The simplest means of programming the flash memory is through the C2 interface using programming tools provided by Silicon Labs or a third party vendor. Firmware may also be loaded into the device to implement code-loader functions or allow non-volatile data storage. To ensure the integrity of flash contents, it is strongly recommended that the on-chip supply monitor be enabled in any system that includes code that writes and/or erases flash memory from software.

#### 4.3.2.1 Flash Lock and Key Functions

Flash writes and erases by user software are protected with a lock and key function. The FLKEY register must be written with the correct key codes, in sequence, before flash operations may be performed. The key codes are 0xA5 and 0xF1. The timing does not matter, but the codes must be written in order. If the key codes are written out of order or the wrong codes are written, flash writes and erases will be disabled until the next system reset. Flash writes and erases will also be disabled if a flash write or erase is attempted before the key codes have been written properly. The flash lock resets after each write or erase; the key codes must be written again before another flash write or erase operation can be performed.

#### 4.3.2.2 Flash Page Erase Procedure

The flash memory is erased one page at a time by firmware using the MOVX write instruction with the address targeted to any byte within the page. Before erasing a page of flash memory, flash write and erase operations must be enabled by setting the PSWE and PSEE bits in the PSCTL register to logic 1 (this directs the MOVX writes to target flash memory and enables page erasure) and writing the flash key codes in sequence to the FLKEY register. The PSWE and PSEE bits remain set until cleared by firmware.

Erase operation applies to an entire page (setting all bytes in the page to 0xFF). To erase an entire page, perform the following steps:

1. Disable interrupts (recommended).
2. Write the first key code to FLKEY: 0xA5.
3. Write the second key code to FLKEY: 0xF1.
4. Set the PSEE bit (register PSCTL).
5. Set the PSWE bit (register PSCTL).
6. Using the MOVX instruction, write a data byte to any location within the page to be erased.
7. Clear the PSWE and PSEE bits.

#### 4.3.2.3 Flash Byte Write Procedure

The flash memory is written by firmware using the MOVX write instruction with the address and data byte to be programmed provided as normal operands in DPTR and A. Before writing to flash memory using MOVX, flash write operations must be enabled by setting the PSWE bit in the PSCTL register to logic 1 (this directs the MOVX writes to target flash memory) and writing the flash key codes in sequence to the FLKEY register. The PSWE bit remains set until cleared by firmware. A write to flash memory can clear bits to logic 0 but cannot set them. A byte location to be programmed should be erased (already set to 0xFF) before a new value is written.

To write a byte of flash, perform the following steps:

1. Disable interrupts (recommended).
2. Write the first key code to FLKEY: 0xA5.
3. Write the second key code to FLKEY: 0xF1.
4. Set the PSWE bit (register PSCTL).
5. Clear the PSEE bit (register PSCTL).
6. Using the MOVX instruction, write a single data byte to the desired location within the desired page.

7. Clear the PSWE bit.

### 4.3.3 Flash Write and Erase Precautions

Any system which contains routines which write or erase flash memory from software involves some risk that the write or erase routines will execute unintentionally if the CPU is operating outside its specified operating range of supply voltage, system clock frequency or temperature. This accidental execution of flash modifying code can result in alteration of flash memory contents causing a system failure that is only recoverable by re-flashing the code in the device.

To help prevent the accidental modification of flash by firmware, hardware restricts flash writes and erasures when the supply monitor is not active and selected as a reset source. As the monitor is enabled and selected as a reset source by default, it is recommended that systems writing or erasing flash simply maintain the default state.

The following sections provide general guidelines for any system which contains routines which write or erase flash from code. Additional flash recommendations and example code can be found in *AN201: Writing to Flash From Firmware*, available from the Silicon Laboratories website.

### Voltage Supply Maintenance and the Supply Monitor

- If the system power supply is subject to voltage or current "spikes," add sufficient transient protection devices to the power supply to ensure that the supply voltages listed in the Absolute Maximum Ratings table are not exceeded.
- Make certain that the minimum supply rise time specification is met. If the system cannot meet this rise time specification, then add an external supply brownout circuit to the RSTb pin of the device that holds the device in reset until the voltage supply reaches the lower limit, and re-asserts RSTb if the supply drops below the low supply limit.
- Do not disable the supply monitor. If the supply monitor must be disabled in the system, firmware should be added to the startup routine to enable the on-chip supply monitor and enable the supply monitor as a reset source as early in code as possible. This should be the first set of instructions executed after the reset vector. For C-based systems, this may involve modifying the startup code added by the C compiler. See your compiler documentation for more details. Make certain that there are no delays in software between enabling the supply monitor and enabling the supply monitor as a reset source.  
**Note:** The supply monitor must be enabled and enabled as a reset source when writing or erasing flash memory. A flash error reset will occur if either condition is not met.
- As an added precaution if the supply monitor is ever disabled, explicitly enable the supply monitor and enable the supply monitor as a reset source inside the functions that write and erase flash memory. The supply monitor enable instructions should be placed just after the instruction to set PSWE to a 1, but before the flash write or erase operation instruction.
- Make certain that all writes to the RSTSRC (Reset Sources) register use direct assignment operators and explicitly do not use the bit-wise operators (such as AND or OR). For example, "RSTSRC = 0x02" is correct. "RSTSRC |= 0x02" is incorrect.
- Make certain that all writes to the RSTSRC register explicitly set the PORSF bit to a 1. Areas to check are initialization code which enables other reset sources, such as the Missing Clock Detector or Comparator, for example, and instructions which force a Software Reset. A global search on "RSTSRC" can quickly verify this.

### PSWE Maintenance

- Reduce the number of places in code where the PSWE bit (in register PSCTL) is set to a 1. There should be exactly one routine in code that sets PSWE to a 1 to write flash bytes and one routine in code that sets PSWE and PSEE both to a 1 to erase flash pages.
- Minimize the number of variable accesses while PSWE is set to a 1. Handle pointer address updates and loop variable maintenance outside the "PSWE = 1;... PSWE = 0;" area.
- Disable interrupts prior to setting PSWE to a 1 and leave them disabled until after PSWE has been reset to 0. Any interrupts posted during the flash write or erase operation will be serviced in priority order after the flash operation has been completed and interrupts have been re-enabled by software.
- Make certain that the flash write and erase pointer variables are not located in XRAM. See your compiler documentation for instructions regarding how to explicitly locate variables in different memory areas.
- Add address bounds checking to the routines that write or erase flash memory to ensure that a routine called with an illegal address does not result in modification of the flash.

### System Clock

- If operating from an external crystal-based source, be advised that crystal performance is susceptible to electrical interference and is sensitive to layout and to changes in temperature. If the system is operating in an electrically noisy environment, use the internal oscillator or use an external CMOS clock.
- If operating from the external oscillator, switch to the internal oscillator during flash write or erase operations. The external oscillator can continue to run, and the CPU can switch back to the external oscillator after the flash operation has completed.

## 4.4 Flash Control Registers

### 4.4.1 PSCTL: Program Store Control

Bit	7	6	5	4	3	2	1	0
Name	Reserved						PSEE	PSWE
Access	R						RW	RW
Reset	0x00						0	0
SFR Address: 0x8F								

Bit	Name	Reset	Access	Description									
7:2	<i>Reserved</i>	<i>Must write reset value.</i>											
1	PSEE	0	RW	<p><b>Program Store Erase Enable.</b></p> <p>Setting this bit (in combination with PSWE) allows an entire page of flash program memory to be erased. If this bit is logic 1 and flash writes are enabled (PSWE is logic 1), a write to flash memory using the MOVX instruction will erase the entire page that contains the location addressed by the MOVX instruction. The value of the data byte written does not matter.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Name</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>ERASE_DISABLED</td> <td>Flash program memory erasure disabled.</td> </tr> <tr> <td>1</td> <td>ERASE_ENABLED</td> <td>Flash program memory erasure enabled.</td> </tr> </tbody> </table>	Value	Name	Description	0	ERASE_DISABLED	Flash program memory erasure disabled.	1	ERASE_ENABLED	Flash program memory erasure enabled.
Value	Name	Description											
0	ERASE_DISABLED	Flash program memory erasure disabled.											
1	ERASE_ENABLED	Flash program memory erasure enabled.											
0	PSWE	0	RW	<p><b>Program Store Write Enable.</b></p> <p>Setting this bit allows writing a byte of data to the flash program memory using the MOVX write instruction. The flash location should be erased before writing data.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Name</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>WRITE_DISABLED</td> <td>Writes to flash program memory disabled.</td> </tr> <tr> <td>1</td> <td>WRITE_ENABLED</td> <td>Writes to flash program memory enabled; the MOVX write instruction targets flash memory.</td> </tr> </tbody> </table>	Value	Name	Description	0	WRITE_DISABLED	Writes to flash program memory disabled.	1	WRITE_ENABLED	Writes to flash program memory enabled; the MOVX write instruction targets flash memory.
Value	Name	Description											
0	WRITE_DISABLED	Writes to flash program memory disabled.											
1	WRITE_ENABLED	Writes to flash program memory enabled; the MOVX write instruction targets flash memory.											

#### 4.4.2 FLKEY: Flash Lock and Key

Bit	7	6	5	4	3	2	1	0
Name	FLKEY							
Access	RW							
Reset	0x00							
SFR Address: 0xB7								

Bit	Name	Reset	Access	Description
7:0	FLKEY	0x00	RW	<b>Flash Lock and Key.</b>
	<p>Write:</p> <p>This register provides a lock and key function for flash erasures and writes. Flash writes and erases are enabled by writing 0xA5 followed by 0xF1 to the FLKEY register. Flash writes and erases are automatically disabled after the next write or erase is complete. If any writes to FLKEY are performed incorrectly, or if a flash write or erase operation is attempted while these operations are disabled, the flash will be permanently locked from writes or erasures until the next device reset. If an application never writes to flash, it can intentionally lock the flash by writing a non-0xA5 value to FLKEY from firmware.</p> <p>Read:</p> <p>When read, bits 1-0 indicate the current flash lock state.</p> <p>00: Flash is write/erase locked.</p> <p>01: The first key code has been written (0xA5).</p> <p>10: Flash is unlocked (writes/erases allowed).</p> <p>11: Flash writes/erases are disabled until the next reset.</p>			

## 5. Device Identification

### 5.1 Device Identification

The SFR map includes registers that may be used to identify the device family (DEVICEID), derivative (DERIVID), and revision (REVID). These SFRs can be read by firmware at runtime to determine the capabilities of the MCU that is executing code. This allows the same firmware image to run on MCUs with different memory sizes and peripherals, and dynamically change functionality to suit the capabilities of that MCU.

### 5.2 Unique Identifier

A 32-bit unique identifier (UID) is pre-loaded upon device reset into the RAM area on all devices. The UID resides in the last four bytes of XRAM on devices which include XRAM, or the last four bytes of the RAM space for devices without XRAM. For devices with the UID in RAM, the UID can be read by firmware using indirect data accesses. For devices with the UID in XRAM, the UID can be read by firmware using MOVX instructions. The UID can also be read through the debug port for all devices.

As the UID appears in RAM, firmware can overwrite the UID during normal operation. The bytes in memory will be automatically reinitialized with the UID value after any device reset. Firmware using this area of memory should always initialize the memory to a known value, as any previous data stored at these locations will be overwritten and not retained through a reset.

**Table 5.1. UID Location in Memory**

Total Device RAM	Memory Segment	Addresses
512 Bytes	XRAM	(MSB) 0x00FF, 0x00FE, 0x00FD, 0x00FC (LSB)
256 Bytes	RAM	(MSB) 0xFF, 0xFE, 0xFD, 0xFC (LSB)

### 5.3 Device Identification Registers

#### 5.3.1 DEVICEID: Device Identification

Bit	7	6	5	4	3	2	1	0
Name	DEVICEID							
Access	R							
Reset	0x30							
SFR Address: 0xB5								

Bit	Name	Reset	Access	Description
7:0	DEVICEID	0x30	R	<b>Device ID.</b> This read-only register returns the 8-bit device ID.

### 5.3.2 DERIVID: Derivative Identification

Bit	7	6	5	4	3	2	1	0
Name	DERIVID							
Access	R							
Reset	Varies							
SFR Address: 0xAD								

Bit	Name	Reset	Access	Description
7:0	DERIVID	Varies	R	<b>Derivative ID.</b>  This read-only register returns the 8-bit derivative ID, which can be used by firmware to identify which device in the product family the code is executing on. The '{R}' tag in the part numbers indicates the device revision letter in the ordering code. The revision letter may be determined by decoding the REVID register.
	Value	Name		Description
	0x01	EFM8BB10F8G_QSOP24		EFM8BB10F8G-{R}-QSOP24
	0x02	EFM8BB10F8G_QFN20		EFM8BB10F8G-{R}-QFN20
	0x03	EFM8BB10F8G_SO-IC16		EFM8BB10F8G-{R}-SOIC16
	0x05	EFM8BB10F4G_QFN20		EFM8BB10F4G-{R}-QFN20
	0x08	EFM8BB10F2G_QFN20		EFM8BB10F2G-{R}-QFN20

### 5.3.3 REVID: Revision Identification

Bit	7	6	5	4	3	2	1	0
Name	REVID							
Access	R							
Reset	Varies							
SFR Address: 0xB6								

Bit	Name	Reset	Access	Description
7:0	REVID	Varies	R	<b>Revision ID.</b>  This read-only register returns the 8-bit revision ID.
	Value	Name		Description
	0x02	REV_A		Revision A

## 6. Interrupts

### 6.1 Introduction

The MCU core includes an extended interrupt system supporting multiple interrupt sources and priority levels. The allocation of interrupt sources between on-chip peripherals and external input pins varies according to the specific version of the device.

Interrupt sources may have one or more associated interrupt-pending flag(s) located in an SFR local to the associated peripheral. When a peripheral or external source meets a valid interrupt condition, the associated interrupt-pending flag is set to logic 1.

If interrupts are enabled for the source, an interrupt request is generated when the interrupt-pending flag is set. As soon as execution of the current instruction is complete, the CPU generates an LCALL to a predetermined address to begin execution of an interrupt service routine (ISR). Each ISR must end with a RETI instruction, which returns program execution to the next instruction that would have been executed if the interrupt request had not occurred. If interrupts are not enabled, the interrupt-pending flag is ignored by the hardware and program execution continues as normal. The interrupt-pending flag is set to logic 1 regardless of whether the interrupt is enabled.

Each interrupt source can be individually enabled or disabled through the use of an associated interrupt enable bit in the IE and EIEN registers. However, interrupts must first be globally enabled by setting the EA bit to logic 1 before the individual interrupt enables are recognized. Setting the EA bit to logic 0 disables all interrupt sources regardless of the individual interrupt-enable settings.

Some interrupt-pending flags are automatically cleared by the hardware when the CPU vectors to the ISR or by other hardware conditions. However, most are not cleared by the hardware and must be cleared by software before returning from the ISR. If an interrupt-pending flag remains set after the CPU completes the return-from-interrupt (RETI) instruction, a new interrupt request will be generated immediately and the CPU will re-enter the ISR after the completion of the next instruction.

### 6.2 Interrupt Sources and Vectors

The CIP51 core supports interrupt sources for each peripheral on the device. Software can simulate an interrupt for many peripherals by setting any interrupt-pending flag to logic 1. If interrupts are enabled for the flag, an interrupt request will be generated and the CPU will vector to the ISR address associated with the interrupt-pending flag. Refer to the data sheet section associated with a particular on-chip peripheral for information regarding valid interrupt conditions for the peripheral and the behavior of its interrupt-pending flag(s).

#### 6.2.1 Interrupt Priorities

Each interrupt source can be individually programmed to one of two priority levels: low or high. A low priority interrupt service routine can be preempted by a high priority interrupt. A high priority interrupt cannot be preempted. Each interrupt has an associated interrupt priority bit in the IP and EIPn registers, which are used to configure its priority level. Low priority is the default. If two interrupts are recognized simultaneously, the interrupt with the higher priority is serviced first. If both interrupts have the same priority level, a fixed order is used to arbitrate, based on the interrupt source's location in the interrupt vector table. Interrupts with a lower number in the vector table have priority.

#### 6.2.2 Interrupt Latency

Interrupt response time depends on the state of the CPU when the interrupt occurs. Pending interrupts are sampled and priority decoded on every system clock cycle. Therefore, the fastest possible response time is 5 system clock cycles: 1 clock cycle to detect the interrupt and 4 clock cycles to complete the LCALL to the ISR. If an interrupt is pending when a RETI is executed, a single instruction is executed before an LCALL is made to service the pending interrupt. Therefore, the maximum response time for an interrupt (when no other interrupt is currently being serviced or the new interrupt is of greater priority) occurs when the CPU is performing a RETI instruction followed by a DIV as the next instruction. In this case, the response time is 18 system clock cycles: 1 clock cycle to detect the interrupt, 5 clock cycles to execute the RETI, 8 clock cycles to complete the DIV instruction and 4 clock cycles to execute the LCALL to the ISR. If the CPU is executing an ISR for an interrupt with equal or higher priority, the new interrupt will not be serviced until the current ISR completes, including the RETI and following instruction. If more than one interrupt is pending when the CPU exits an ISR, the CPU will service the next highest priority interrupt that is pending.

### 6.2.3 Interrupt Summary

**Table 6.1. Interrupt Priority Table**

Interrupt Source	Vector	Priority	Primary Enable	Auxiliary Enable(s)	Pending Flag(s)
Reset	0x0000	Top	-	-	-
External Interrupt 0	0x0003	0	IE_EX0	-	TCON_IE0

	Value	Name		Description
	0	LOW		SMB0 interrupt set to low priority level.
	1	HIGH		SMB0 interrupt set to high priority level.

## 7. Power Management and Internal Regulators

### 7.1 Introduction

All internal circuitry draws power from the VDD supply pin. External I/O pins are powered from the VIO supply voltage (or VDD on devices without a separate VIO connection), while most of the internal circuitry is supplied by an on-chip LDO regulator. Control over the device power can be achieved by enabling/disabling individual peripherals as needed. Each analog peripheral can be disabled when not in use and placed in low power mode. Digital peripherals, such as timers and serial buses, have their clocks gated off and draw little power when they are not in use.

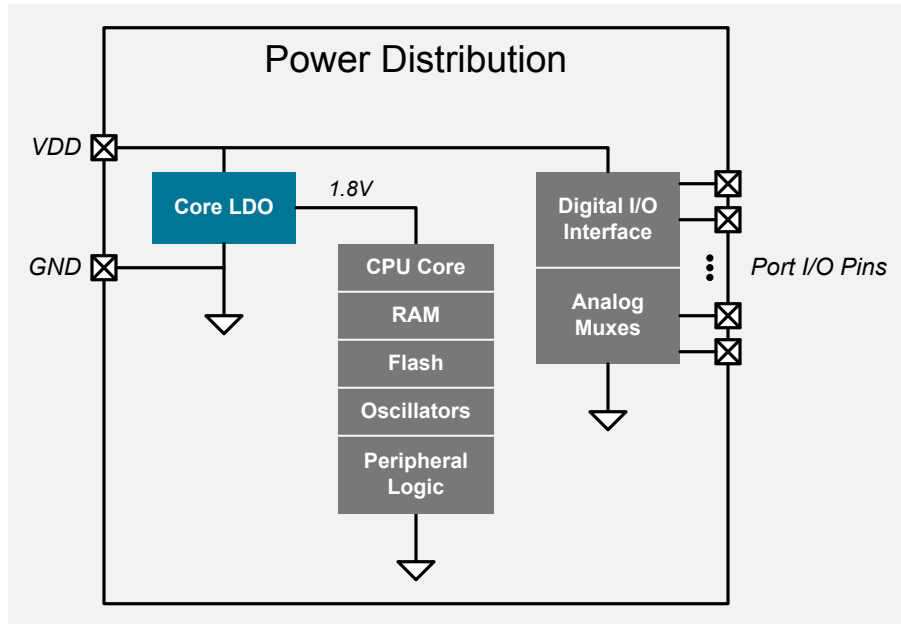

Figure 7.1. Power System Block Diagram

Table 7.1. Power Modes

Power Mode	Details	Mode Entry	Wake-Up Sources
Normal	Core and all peripherals clocked and fully operational	—	—
Idle	<ul style="list-style-type: none"> <li>Core halted</li> <li>All peripherals clocked and fully operational</li> <li>Code resumes execution on wake event</li> </ul>	Set IDLE bit in PCON0	Any interrupt
Shutdown	<ul style="list-style-type: none"> <li>All internal power nets shut down</li> <li>Pins retain state</li> <li>Exit on pin or power-on reset</li> </ul>	<ol style="list-style-type: none"> <li>Set STOPCF bit in REG0CN</li> <li>Set STOP bit in PCON0</li> </ol>	<ul style="list-style-type: none"> <li>RSTb pin reset</li> <li>Power-on reset</li> </ul>

## 7.2 Features

- Supports four power modes:
  1. Normal mode: Core and all peripherals fully operational.
  2. Idle mode: Core halted, peripherals fully operational, core waiting for interrupt to continue.
  3. Shutdown mode: All clocks stopped and internal LDO shut off, device waiting for POR or pin reset.

Note: Legacy 8051 Stop mode is also supported, where internal LDO remains active, but a device reset is required to wake.

- Fully internal core LDO supplies power to majority of blocks.

## 7.3 Idle Mode

In idle mode, CPU core execution is halted while any enabled peripherals and clocks remain active. Power consumption in idle mode is dependent upon the system clock frequency and any active peripherals.

Setting the IDLE bit in the PCON0 register causes the hardware to halt the CPU and enter idle mode as soon as the instruction that sets the bit completes execution. All internal registers and memory maintain their original data. All analog and digital peripherals can remain active during idle mode.

Idle mode is terminated when an enabled interrupt is asserted or a reset occurs. The assertion of an enabled interrupt will cause the IDLE bit to be cleared and the CPU to resume operation. The pending interrupt will be serviced and the next instruction to be executed after the return from interrupt (RETI) will be the instruction immediately following the one that set the IDLE bit. If idle mode is terminated by an internal or external reset, the CIP-51 performs a normal reset sequence and begins program execution at address 0x0000.

**Note:** If the instruction following the write of the IDLE bit is a single-byte instruction and an interrupt occurs during the execution phase of the instruction that sets the IDLE bit, the CPU may not wake from idle mode when a future interrupt occurs. Therefore, instructions that set the IDLE bit should be followed by an instruction that has two or more opcode bytes. For example:

```
// in 'C':
PCON0 |= 0x01; // set IDLE bit
PCON0 = PCON0; // ... followed by a 3-cycle dummy instruction

; in assembly:
ORL PCON0, #01h ; set IDLE bit
MOV PCON0, PCON0 ; ... followed by a 3-cycle dummy instruction
```

If enabled, the Watchdog Timer (WDT) will eventually cause an internal watchdog reset and thereby terminate the Idle mode. This feature protects the system from an unintended permanent shutdown in the event of an inadvertent write to the PCON0 register. If this behavior is not desired, the WDT may be disabled by software prior to entering the idle mode if the WDT was initially configured to allow this operation. This provides the opportunity for additional power savings, allowing the system to remain in the idle mode indefinitely, waiting for an external stimulus to wake up the system.

## 7.4 Stop Mode

In stop mode, the CPU is halted and peripheral clocks are stopped. Analog peripherals remain in their selected states.

Setting the STOP bit in the PCON0 register causes the controller core to enter stop mode as soon as the instruction that sets the bit completes execution. Before entering stop mode, the system clock must be sourced by HFOSC0. In stop mode, the CPU and internal clocks are stopped. Analog peripherals may remain enabled, but will not be provided a clock. Each analog peripheral may be shut down individually by firmware prior to entering stop mode. Stop mode can only be terminated by an internal or external reset. On reset, the device performs the normal reset sequence and begins program execution at address 0x0000.

If enabled as a reset source, the missing clock detector will cause an internal reset and thereby terminate the stop mode. If this reset is undesirable in the system, and the CPU is to be placed in stop mode for longer than the missing clock detector timeout, the missing clock detector should be disabled in firmware prior to setting the STOP bit.

## 7.5 Shutdown Mode

In shutdown mode, the CPU is halted and the internal LDO is powered down. External I/O will retain their configured states.

To enter Shutdown mode, firmware should set the STOPCF bit in the regulator control register to 1, and then set the STOP bit in PCON0. In Shutdown, the RSTb pin and a full power cycle of the device are the only methods of generating a reset and waking the device.

**Note:** In Shutdown mode, all internal device circuitry is powered down, and no RAM nor registers are retained. The debug circuitry will not be able to connect to a device while it is in Shutdown. Coming out of Shutdown mode, whether by POR or pin reset, will appear as a power-on reset of the device.

## 7.6 Power Management Control Registers

2:0	<i>Reserved</i>	<i>Must write reset value.</i>											

## 8. Clocking and Oscillators

### 8.1 Introduction

The CPU core and peripheral subsystem may be clocked by both internal and external oscillator resources. By default, the system clock comes up running from the 24.5 MHz oscillator divided by 8.

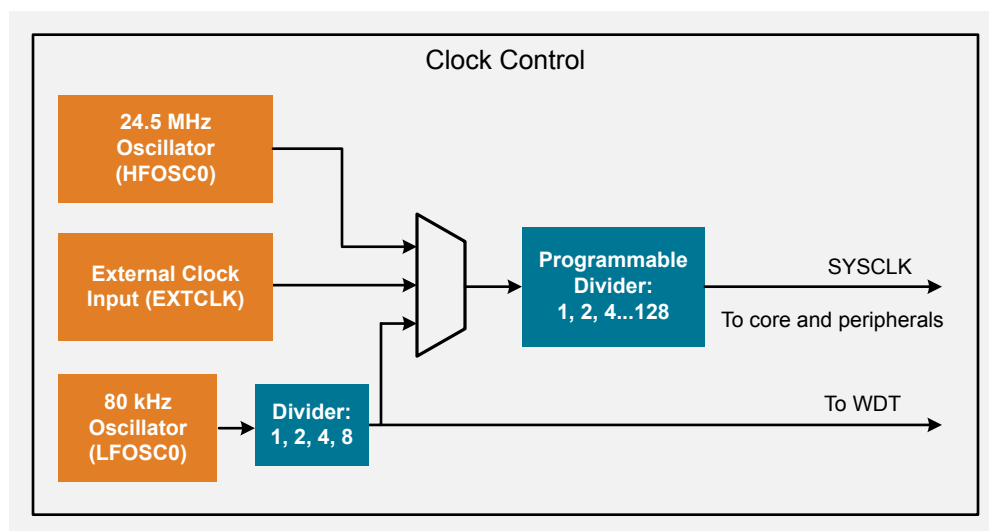

Figure 8.1. Clock Control Block Diagram

### 8.2 Features

- Provides clock to core and peripherals.
- 24.5 MHz internal oscillator (HFOSC0), accurate to  $\pm 2\%$  over supply and temperature corners.
- 80 kHz low-frequency oscillator (LFOSC0).
- External CMOS clock input (EXTCLK).
- Clock divider with eight settings for flexible clock scaling: Divide the selected clock source by 1, 2, 4, 8, 16, 32, 64, or 128.

### 8.3 Functional Description

#### 8.3.1 Clock Selection

The CLKSEL register is used to select the clock source for the system (SYSCLK). The CLKSL field selects which oscillator source is used as the system clock, while CLKDIV controls the programmable divider. When an internal oscillator source is selected as the SYSCLK, the external oscillator may still clock certain peripherals. In these cases, the external oscillator source is synchronized to the SYSCLK source. The system clock may be switched on-the-fly between any of the oscillator sources so long as the selected clock source is enabled and has settled, and CLKDIV may be changed at any time.

**Note:** Some device families do place restrictions on the difference in operating frequency when switching clock sources. Please see the CLKSEL register description for details.

#### 8.3.2 HFOSC0 24.5 MHz Internal Oscillator

HFOSC0 is a programmable internal high-frequency oscillator that is factory-calibrated to 24.5 MHz. The oscillator is automatically enabled when it is requested. The oscillator period can be adjusted via the HFO0CAL register to obtain other frequencies.

#### 8.3.3 LFOSC0 80 kHz Internal Oscillator

LFOSC0 is a programmable low-frequency oscillator, factory calibrated to a nominal frequency of 80 kHz. A dedicated divider at the oscillator output is capable of dividing the output clock by 1, 2, 4, or 8, using the OSCLD bits in the LFO0CN register. The OSCLF bits can be used to coarsely adjust the oscillator's output frequency.

The LFOSC0 circuit requires very little start-up time and may be selected as the system clock immediately following the register write which enables the oscillator.

## Calibrating LFOSC0

On-chip calibration of the LFOSC0 can be performed using a timer to capture the oscillator period, when running from a known time base. When a timer is configured for L-F Oscillator capture mode, a rising edge of the low-frequency oscillator's output will cause a capture event on the corresponding timer. As a capture event occurs, the current timer value is copied into the timer reload registers. By recording the difference between two successive timer capture values, the low-frequency oscillator's period can be calculated. The OSCLF bits can then be adjusted to produce the desired oscillator frequency.

### 8.3.4 External Clock

An external CMOS clock source is also supported as a core clock source. The EXTCLK pin on the device serves as the external clock input when running in this mode. The EXTCLK input may also be used to clock certain digital peripherals (e.g., Timers, PCA, etc.) while SYSCLK runs from one of the internal oscillator sources. When not selected as the SYSCLK source, the EXTCLK input is always re-synchronized to SYSCLK.

**Note:** When selecting the EXTCLK pin as a clock input source, the pin should be skipped in the crossbar and configured as a digital input. Firmware should ensure that the external clock source is present or enable the missing clock detector before switching the CLKSL field.

## 8.4 Clocking and Oscillator Control Registers

### 8.4.1 CLKSEL: Clock Select

Bit	7	6	5	4	3	2	1	0
Name	Reserved	CLKDIV			Reserved		CLKSL	
Access	R	RW			R		RW

SFR Address: 0xC7								

Bit	Name	Reset	Access	Description
7:0	HFO0CAL	Varies	RW	<b>Oscillator Calibration.</b> These bits determine the period for high frequency oscillator 0. When set to 0x00, the oscillator operates at its fastest setting. When set to 0xFF, the oscillator operates at its slowest setting. The reset value is factory calibrated, and the oscillator will revert to the calibrated frequency upon reset.

### 8.4.3 LFO0CN: Low Frequency Oscillator Control

Bit	7	6	5	4	3	2	1	0
Name	OSCLEN	OSCLRDY	OSCLF				OSCLD	
Access	RW	R	RW				RW	
Reset	0	1	Varies				0x0	
SFR Address: 0xB1								

Bit	Name	Reset	Access	Description
7	OSCLEN	0	RW	<b>Internal L-F Oscillator Enable.</b>  This bit enables the internal low-frequency oscillator. Note that the low-frequency oscillator is automatically enabled when the watchdog timer is active.
	Value	Name	Description	
	0	DISABLED	Internal L-F Oscillator Disabled.	
	1	ENABLED	Internal L-F Oscillator Enabled.	
6	OSCLRDY	1	R	<b>Internal L-F Oscillator Ready.</b>  Value Name Description
	0	NOT_SET	Internal L-F Oscillator frequency not stabilized.	
	1	SET	Internal L-F Oscillator frequency stabilized.	
5:2	OSCLF	Varies	RW	<b>Internal L-F Oscillator Frequency Control.</b>  Fine-tune control bits for the Internal L-F oscillator frequency. When set to 0000b, the L-F oscillator operates at its fastest setting. When set to 1111b, the L-F oscillator operates at its slowest setting. The OSCLF bits should only be changed by firmware when the L-F oscillator is disabled (OSCLEN = 0).
1:0	OSCLD	0x0	RW	<b>Internal L-F Oscillator Divider Select.</b>  Value Name Description
	0x0	DIVIDE_BY_8	Divide by 8 selected.	
	0x1	DIVIDE_BY_4	Divide by 4 selected.	
	0x2	DIVIDE_BY_2	Divide by 2 selected.	
	0x3	DIVIDE_BY_1	Divide by 1 selected.	
OSCLRDY is only set back to 0 in the event of a device reset or a change to the OSCLD bits.				

## 9. Reset Sources and Power Supply Monitor

### 9.1 Introduction

Reset circuitry allows the controller to be easily placed in a predefined default condition. On entry to this reset state, the following occur:

- The core halts program execution.
- Module registers are initialized to their defined reset values unless the bits reset only with a power-on reset.
- External port pins are forced to a known state.
- Interrupts and timers are disabled.

All registers are reset to the predefined values noted in the register descriptions unless the bits only reset with a power-on reset. The contents of RAM are unaffected during a reset; any previously stored data is preserved as long as power is not lost. The Port I/O latches are reset to 1 in open-drain mode. Weak pullups are enabled during and after the reset. For Supply Monitor and power-on resets, the RSTb pin is driven low until the device exits the reset state. On exit from the reset state, the program counter (PC) is reset, and the system clock defaults to an internal oscillator. The Watchdog Timer is enabled, and program execution begins at location 0x0000.

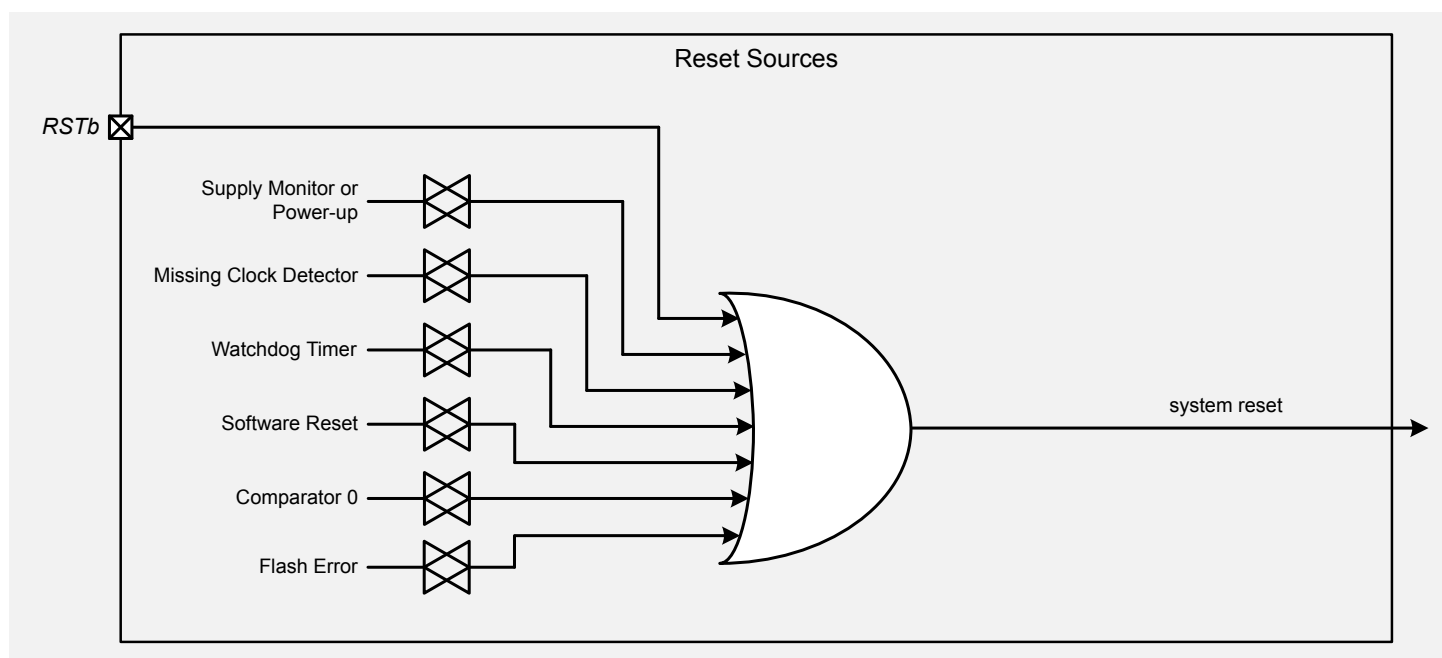

Figure 9.1. Reset Sources Block Diagram

### 9.2 Features

Reset sources on the device include the following:

- Power-on reset
- External reset pin
- Comparator reset
- Software-triggered reset
- Supply monitor reset (monitors VDD supply)
- Watchdog timer reset
- Missing clock detector reset
- Flash error reset

## 9.3 Functional Description

### 9.3.1 Device Reset

Upon entering a reset state from any source, the following events occur:

- The processor core halts program execution.
- Special Function Registers (SFRs) are initialized to their defined reset values.
- External port pins are placed in a known state.
- Interrupts and timers are disabled.

SFRs are reset to the predefined reset values noted in the detailed register descriptions. The contents of internal data memory are unaffected during a reset; any previously stored data is preserved. However, since the stack pointer SFR is reset, the stack is effectively lost, even though the data on the stack is not altered.

The port I/O latches are reset to 0xFF (all logic ones) in open-drain mode. Weak pullups are enabled during and after the reset. For Supply Monitor and power-on resets, the RSTb pin is driven low until the device exits the reset state.

**Note:** During a power-on event, there may be a short delay before the POR circuitry fires and the RSTb pin is driven low. During that time, the RSTb pin will be weakly pulled to the supply pin.

On exit from the reset state, the program counter (PC) is reset, the watchdog timer is enabled, and the system clock defaults to an internal oscillator. Program execution begins at location 0x0000.

### 9.3.2 Power-On Reset

During power-up, the POR circuit fires. When POR fires, the device is held in a reset state and the RSTb pin is driven low until the supply voltage settles above  $V_{RST}$ . Two delays are present during the supply ramp time. First, a delay occurs before the POR circuitry fires and pulls the RSTb pin low. A second delay occurs before the device is released from reset; the delay decreases as the supply ramp time increases (supply ramp time is defined as how fast the supply pin ramps from 0 V to  $V_{RST}$ ). For ramp times less than 1 ms, the power-on reset time ( $T_{POR}$ ) is typically less than 0.3 ms. Additionally, the power supply must reach  $V_{RST}$  before the POR circuit releases the device from reset.

On exit from a power-on reset, the PORSF flag is set by hardware to logic 1. When PORSF is set, all of the other reset flags in the RSTSRC register are indeterminate. (PORSF is cleared by all other resets.) Since all resets cause program execution to begin at the same location (0x0000), software can read the PORSF flag to determine if a power-up was the cause of reset. The content of internal data memory should be assumed to be undefined after a power-on reset. The supply monitor is enabled following a power-on reset.

Figure 9.2. Power-On Reset Timing

### 9.3.3 Supply Monitor Reset

The supply monitor senses the voltage on the device's supply pin and can generate a reset if the supply drops below the corresponding threshold. This monitor is enabled and enabled as a reset source after initial power-on to protect the device until the supply is an adequate and stable voltage. When enabled and selected as a reset source, any power down transition or power irregularity that causes the supply to drop below the reset threshold will drive the RSTb pin low and hold the core in a reset state. When the supply returns to a level above the reset threshold, the monitor will release the core from the reset state. The reset status can then be read using the device reset sources module. After a power-fail reset, the PORF flag reads 1 and all of the other reset flags in the RSTSRC register are indeterminate. The power-on reset delay ( $t_{POR}$ ) is not incurred after a supply monitor reset. The contents of RAM should be presumed invalid after a supply monitor reset. The enable state of the supply monitor and its selection as a reset source is not altered by device resets. For example, if the supply monitor is de-selected as a reset source and disabled by software using the VDMEN bit in the VDM0CN register, and then firmware performs a software reset, the supply monitor will remain disabled and de-selected after the reset. To protect the integrity of flash contents, the supply monitor must be enabled and selected as a reset source if software contains routines that erase or write flash memory. If the supply monitor is not enabled, any erase or write performed on flash memory will be ignored.

Figure 9.3. Reset Sources

### 9.3.4 External Reset

The external RSTb pin provides a means for external circuitry to force the device into a reset state. Asserting an active-low signal on the RSTb pin generates a reset; an external pullup and/or decoupling of the RSTb pin may be necessary to avoid erroneous noise-induced resets. The PINRSF flag is set on exit from an external reset.

### 9.3.5 Missing Clock Detector Reset

The Missing Clock Detector (MCD) is a one-shot circuit that is triggered by the system clock. If the system clock remains high or low for more than the MCD time window, the one-shot will time out and generate a reset. After a MCD reset, the MCDRSF flag will read 1, signifying the MCD as the reset source; otherwise, this bit reads 0. Writing a 1 to the MCDRSF bit enables the Missing Clock Detector; writing a 0 disables it. The state of the RSTb pin is unaffected by this reset.

### 9.3.6 Comparator (CMP0) Reset

Comparator0 can be configured as a reset source by writing a 1 to the CORSEF flag. Comparator0 should be enabled and allowed to settle prior to writing to CORSEF to prevent any turn-on chatter on the output from generating an unwanted reset. The Comparator0 reset is active-low: if the non-inverting input voltage (on CP0+) is less than the inverting input voltage (on CP0-), the device is put into the reset state. After a Comparator0 reset, the CORSEF flag will read 1 signifying Comparator0 as the reset source; otherwise, this bit reads 0. The state of the RSTb pin is unaffected by this reset.

### 9.3.7 Watchdog Timer Reset

The programmable Watchdog Timer (WDT) can be used to prevent software from running out of control during a system malfunction. The WDT function can be enabled or disabled by software as described in the watchdog timer section. If a system malfunction prevents user software from updating the WDT, a reset is generated and the WDTRSF bit is set to 1. The state of the RSTb pin is unaffected by this reset.

### 9.3.8 Flash Error Reset

If a flash read/write/erase or program read targets an illegal address, a system reset is generated. This may occur due to any of the following:

- A flash write or erase is attempted above user code space.
- A flash read is attempted above user code space.
- A program read is attempted above user code space (i.e., a branch instruction to the reserved area).
- A flash read, write or erase attempt is restricted due to a flash security setting.

The FERROR bit is set following a flash error reset. The state of the RSTb pin is unaffected by this reset.

### 9.3.9 Software Reset

Software may force a reset by writing a 1 to the SWRSF bit. The SWRSF bit will read 1 following a software forced reset. The state of the RSTb pin is unaffected by this reset.

## 9.4 Reset Sources and Supply Monitor Control Registers

### 9.4.1 RSTSRC: Reset Source

Bit	7	6	5	4	3	2	1	0
Name	Reserved	FERROR	CORSEF	SWRSF	WDTRSF	MCDRSF	PORSF	PINRSF
Access	RW	R	RW	RW	R	RW	RW	R
Reset	Varies	Varies	Varies	Varies	Varies	Varies	Varies	Varies

SFR Address: 0xEF

Bit	Name	Reset	Access	Description
7	<i>Reserved</i>	<i>Must write reset value.</i>		
6	FERROR	Varies	R	<b>Flash Error Reset Flag.</b> This read-only bit is set to '1' if a flash read/write/erase error caused the last reset.
5	CORSEF	Varies	RW	<b>Comparator0 Reset Enable and Flag.</b> Read: This bit reads 1 if Comparator 0 caused the last reset. Write: Writing a 1 to this bit enables Comparator 0 (active-low) as a reset source.
4	SWRSF	Varies	RW	<b>Software Reset Force and Flag.</b> Read: This bit reads 1 if last reset was caused by a write to SWRSF. Write: Writing a 1 to this bit forces a system reset.
3	WDTRSF	Varies	R	<b>Watchdog Timer Reset Flag.</b> This read-only bit is set to '1' if a watchdog timer overflow caused the last reset.
2	MCDRSF	Varies	RW	<b>Missing Clock Detector Enable and Flag.</b> Read: This bit reads 1 if a missing clock detector timeout caused the last reset. Write: Writing a 1 to this bit enables the missing clock detector. The MCD triggers a reset if a missing clock condition is detected.
1	PORSF	Varies	RW	<b>Power-On / Supply Monitor Reset Flag, and Supply Monitor Reset Enable.</b> Read: This bit reads 1 anytime a power-on or supply monitor reset has occurred. Write: Writing a 1 to this bit enables the supply monitor as a reset source.
0	PINRSF	Varies	R	<b>HW Pin Reset Flag.</b> This read-only bit is set to '1' if the RSTb pin caused the last reset.

Reads and writes of the RSTSRC register access different logic in the device. Reading the register always returns status information to indicate the source of the most recent reset. Writing to the register activates certain options as reset sources. It is recommended to not use any kind of read-modify-write operation on this register.

When the PORSF bit reads back '1' all other RSTSRC flags are indeterminate.

Writing '1' to the PORSF bit when the supply monitor is not enabled and stabilized may cause a system reset.

### 9.4.2 VDM0CN: Supply Monitor Control

Bit	7	6	5	4	3	2	1	0
Name	VDMEN	VDDSTAT	Reserved					
Access	RW	R	R					
Reset	Varies	Varies	Varies					
SFR Address: 0xFF								

Bit	Name	Reset	Access	Description									
7	VDMEN	Varies	RW	<p><b>Supply Monitor Enable.</b></p> <p>This bit turns the supply monitor circuit on/off. The supply monitor cannot generate system resets until it is also selected as a reset source in register RSTSRC. Selecting the supply monitor as a reset source before it has stabilized may generate a system reset. In systems where this reset would be undesirable, a delay should be introduced between enabling the supply monitor and selecting it as a reset source.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Name</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>DISABLED</td> <td>Supply Monitor Disabled.</td> </tr> <tr> <td>1</td> <td>ENABLED</td> <td>Supply Monitor Enabled.</td> </tr> </tbody> </table>	Value	Name	Description	0	DISABLED	Supply Monitor Disabled.	1	ENABLED	Supply Monitor Enabled.
Value	Name	Description											
0	DISABLED	Supply Monitor Disabled.											
1	ENABLED	Supply Monitor Enabled.											
6	VDDSTAT	Varies	R	<p><b>Supply Status.</b></p> <p>This bit indicates the current power supply status (supply monitor output).</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Name</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>BELOW</td> <td><math>V_{DD}</math> is at or below the supply monitor threshold.</td> </tr> <tr> <td>1</td> <td>ABOVE</td> <td><math>V_{DD}</math> is above the supply monitor threshold.</td> </tr> </tbody> </table>	Value	Name	Description	0	BELOW	$V_{DD}$ is at or below the supply monitor threshold.	1	ABOVE	$V_{DD}$ is above the supply monitor threshold.
Value	Name	Description											
0	BELOW	$V_{DD}$ is at or below the supply monitor threshold.											
1	ABOVE	$V_{DD}$ is above the supply monitor threshold.											
5:0	Reserved	Must write reset value.											

## 10. CIP-51 Microcontroller Core

### 10.1 Introduction

The CIP-51 microcontroller core is a high-speed, pipelined, 8-bit core utilizing the standard MCS-51™ instruction set. Any standard 803x/805x assemblers and compilers can be used to develop software. The MCU family has a superset of all the peripherals included with a standard 8051. The CIP-51 includes on-chip debug hardware and interfaces directly with the analog and digital subsystems providing a complete data acquisition or control system solution.

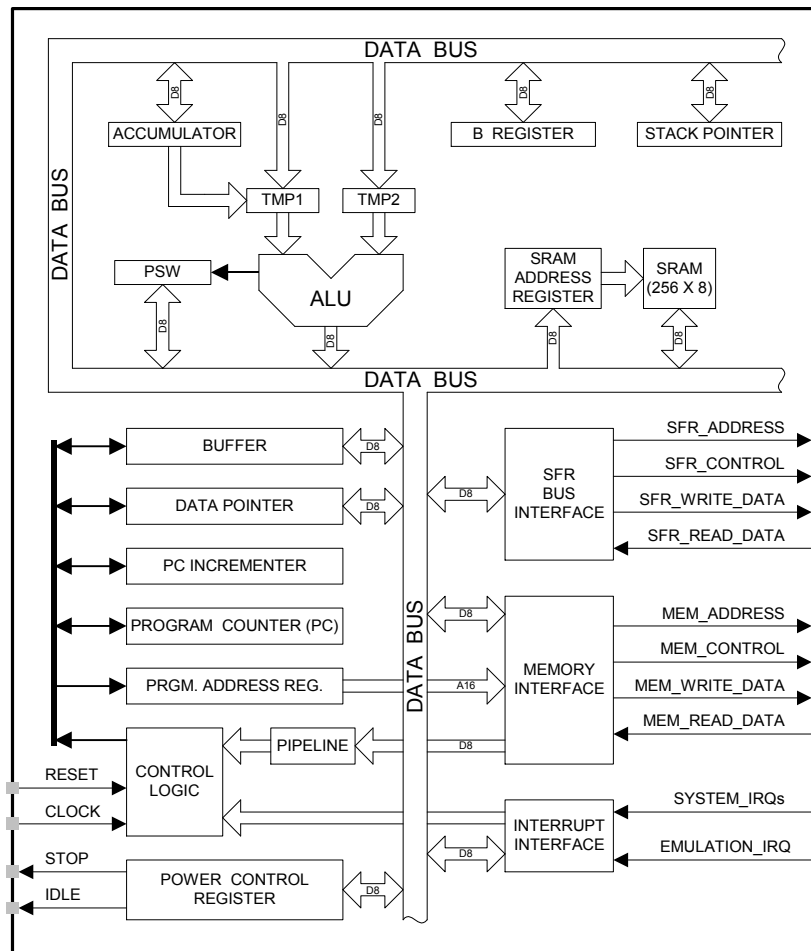

Figure 10.1. CIP-51 Block Diagram

## Performance

The CIP-51 employs a pipelined architecture that greatly increases its instruction throughput over the standard 8051 architecture. The CIP-51 core executes 76 of its 109 instructions in one or two clock cycles, with no instructions taking more than eight clock cycles. The table below shows the distribution of instructions vs. the number of clock cycles required for execution.

**Table 10.1. Instruction Execution Timing**

Clocks to Execute	1	2	2 or 3	3	3 or 4	4	4 or 5	5	8
Number of Instructions	26	50	5	14	7	3	1	2	1
Notes: 1. Conditional branch instructions (indicated by "2 or 3", "3 or 4" and "4 or 5") require an extra clock cycle if the branch is taken.									

## 10.2 Features

The CIP-51 Microcontroller core implements the standard 8051 organization and peripherals as well as additional custom peripherals and functions to extend its capability. The CIP-51 includes the following features:

- Fast, efficient, pipelined architecture.
- Fully compatible with MCS-51 instruction set.
- 0 to 25 MHz operating clock frequency.
- 25 MIPS peak throughput with 25 MHz clock.
- Extended interrupt handler.
- Power management modes.
- On-chip debug logic.
- Program and data memory security.

## 10.3 Functional Description

### 10.3.1 Programming and Debugging Support

In-system programming of the flash program memory and communication with on-chip debug support logic is accomplished via the Silicon Labs 2-Wire development interface (C2).

The on-chip debug support logic facilitates full speed in-circuit debugging, allowing the setting of hardware breakpoints, starting, stopping and single stepping through program execution (including interrupt service routines), examination of the program's call stack, and reading/writing the contents of registers and memory. This method of on-chip debugging is completely non-intrusive, requiring no RAM, stack, timers, or other on-chip resources.

The CIP-51 is supported by development tools from Silicon Labs and third party vendors. Silicon Labs provides an integrated development environment (IDE) including editor, debugger and programmer. The IDE's debugger and programmer interface to the CIP-51 via the C2 interface to provide fast and efficient in-system device programming and debugging. Third party macro assemblers and C compilers are also available.

### 10.3.2 Instruction Set

The instruction set of the CIP-51 System Controller is fully compatible with the standard MCS-51™ instruction set. Standard 8051 development tools can be used to develop software for the CIP-51. All CIP-51 instructions are the binary and functional equivalent of their MCS-51™ counterparts, including opcodes, addressing modes and effect on PSW flags. However, instruction timing is much faster than that of the standard 8051.

All instruction timing on the CIP-51 controller is based directly on the core clock timing. This is in contrast to many other 8-bit architectures, where a distinction is made between machine cycles and clock cycles, with machine cycles taking multiple core clock cycles.

Due to the pipelined architecture of the CIP-51, most instructions execute in the same number of clock cycles as there are program bytes in the instruction. Conditional branch instructions take one less clock cycle to complete when the branch is not taken as opposed to when the branch is taken. The following table summarizes the instruction set, including the mnemonic, number of bytes, and number of clock cycles for each instruction.

**Table 10.2. CIP-51 Instruction Set Summary**

Mnemonic	Description	Bytes	Clock Cycles
Arithmetic Operations			
ADD A, Rn	Add register to A	1	1
ADD A, direct	Add direct byte to A	2	2
ADD A, @Ri	Add indirect RAM to A	1	2
ADD A, #data	Add immediate to A	2	2
ADDC A, Rn	Add register to A with carry	1	1
ADDC A, direct	Add direct byte to A with carry	2	2
ADDC A, @Ri	Add indirect RAM to A with carry	1	2
ADDC A, #data	Add immediate to A with carry	2	2
SUBB A, Rn	Subtract register from A with borrow	1	1
SUBB A, direct	Subtract direct byte from A with borrow	2	2
SUBB A, @Ri	Subtract indirect RAM from A with borrow	1	2
SUBB A, #data	Subtract immediate from A with borrow	2	2
INC A	Increment A	1	1
INC Rn	Increment register	1	1
INC direct	Increment direct byte	2	2
INC @Ri	Increment indirect RAM	1	2
DEC A	Decrement A	1	1
DEC Rn	Decrement register	1	1
DEC direct	Decrement direct byte	2	2
DEC @Ri	Decrement indirect RAM	1	2
INC DPTR	Increment Data Pointer	1	1
MUL AB	Multiply A and B	1	4
DIV AB	Divide A by B	1	8
DA A	Decimal adjust A	1	1
Logical Operations			
ANL A, Rn	AND Register to A	1	1
ANL A, direct	AND direct byte to A	2	2

Mnemonic	Description	Bytes	Clock Cycles
ANL A, @Ri	AND indirect RAM to A	1	2
ANL A, #data	AND immediate to A	2	2
ANL direct, A	AND A to direct byte	2	2
ANL direct, #data	AND immediate to direct byte	3	3
ORL A, Rn	OR Register to A	1	1
ORL A, direct	OR direct byte to A	2	2
ORL A, @Ri	OR indirect RAM to A	1	2
ORL A, #data	OR immediate to A	2	2
ORL direct, A	OR A to direct byte	2	2
ORL direct, #data	OR immediate to direct byte	3	3
XRL A, Rn	Exclusive-OR Register to A	1	1
XRL A, direct	Exclusive-OR direct byte to A	2	2
XRL A, @Ri	Exclusive-OR indirect RAM to A	1	2
XRL A, #data	Exclusive-OR immediate to A	2	2
XRL direct, A	Exclusive-OR A to direct byte	2	2
XRL direct, #data	Exclusive-OR immediate to direct byte	3	3
CLR A	Clear A	1	1
CPL A	Complement A	1	1
RL A	Rotate A left	1	1
RLC A	Rotate A left through Carry	1	1
RR A	Rotate A right	1	1
RRC A	Rotate A right through Carry	1	1
SWAP A	Swap nibbles of A	1	1
Data Transfer			
MOV A, Rn	Move Register to A	1	1
MOV A, direct	Move direct byte to A	2	2
MOV A, @Ri	Move indirect RAM to A	1	2
MOV A, #data	Move immediate to A	2	2
MOV Rn, A	Move A to Register	1	1
MOV Rn, direct	Move direct byte to Register	2	2
MOV Rn, #data	Move immediate to Register	2	2
MOV direct, A	Move A to direct byte	2	2
MOV direct, Rn	Move Register to direct byte	2	2
MOV direct, direct	Move direct byte to direct byte	3	3
MOV direct, @Ri	Move indirect RAM to direct byte	2	2
MOV direct, #data	Move immediate to direct byte	3	3
MOV @Ri, A	Move A to indirect RAM	1	2

Mnemonic	Description	Bytes	Clock Cycles
MOV @Ri, direct	Move direct byte to indirect RAM	2	2
MOV @Ri, #data	Move immediate to indirect RAM	2	2
MOV DPTR, #data16	Load DPTR with 16-bit constant	3	3
MOVC A, @A+DPTR	Move code byte relative DPTR to A	1	3
MOVC A, @A+PC	Move code byte relative PC to A	1	3
MOVX A, @Ri	Move external data (8-bit address) to A	1	3
MOVX @Ri, A	Move A to external data (8-bit address)	1	3
MOVX A, @DPTR	Move external data (16-bit address) to A	1	3
MOVX @DPTR, A	Move A to external data (16-bit address)	1	3
PUSH direct	Push direct byte onto stack	2	2
POP direct	Pop direct byte from stack	2	2
XCH A, Rn	Exchange Register with A	1	1
XCH A, direct	Exchange direct byte with A	2	2
XCH A, @Ri	Exchange indirect RAM with A	1	2
XCHD A, @Ri	Exchange low nibble of indirect RAM with A	1	2
<b>Boolean Manipulation</b>			
CLR C	Clear Carry	1	1
CLR bit	Clear direct bit	2	2
SETB C	Set Carry	1	1
SETB bit	Set direct bit	2	2
CPL C	Complement Carry	1	1
CPL bit	Complement direct bit	2	2
ANL C, bit	AND direct bit to Carry	2	2
ANL C, /bit	AND complement of direct bit to Carry	2	2
ORL C, bit	OR direct bit to carry	2	2
ORL C, /bit	OR complement of direct bit to Carry	2	2
MOV C, bit	Move direct bit to Carry	2	2
MOV bit, C	Move Carry to direct bit	2	2
JC rel	Jump if Carry is set	2	2 or 3
JNC rel	Jump if Carry is not set	2	2 or 3
JB bit, rel	Jump if direct bit is set	3	3 or 4
JNB bit, rel	Jump if direct bit is not set	3	3 or 4
JBC bit, rel	Jump if direct bit is set and clear bit	3	3 or 4
<b>Program Branching</b>			
ACALL addr11	Absolute subroutine call	2	3
LCALL addr16	Long subroutine call	3	4
RET	Return from subroutine	1	5

Mnemonic	Description	Bytes	Clock Cycles
RETI	Return from interrupt	1	5
AJMP addr11	Absolute jump	2	3
LJMP addr16	Long jump	3	4
SJMP rel	Short jump (relative address)	2	3
JMP @A+DPTR	Jump indirect relative to DPTR	1	3
JZ rel	Jump if A equals zero	2	2 or 3
JNZ rel	Jump if A does not equal zero	2	2 or 3
CJNE A, direct, rel	Compare direct byte to A and jump if not equal	3	3 or 4
CJNE A, #data, rel	Compare immediate to A and jump if not equal	3	3 or 4
CJNE Rn, #data, rel	Compare immediate to Register and jump if not equal	3	3 or 4
CJNE @Ri, #data, rel	Compare immediate to indirect and jump if not equal	3	4 or 5
DJNZ Rn, rel	Decrement Register and jump if not zero	2	2 or 3
DJNZ direct, rel	Decrement direct byte and jump if not zero	3	3 or 4
NOP	No operation	1	1

Notes:

- **Rn**: Register R0–R7 of the currently selected register bank.
- **@Ri**: Data RAM location addressed indirectly through R0 or R1.
- **rel**: 8-bit, signed (twos complement) offset relative to the first byte of the following instruction. Used by SJMP and all conditional jumps.
- **direct**: 8-bit internal data location's address. This could be a direct-access Data RAM location (0x00–0x7F) or an SFR (0x80–0xFF).
- **#data**: 8-bit constant.
- **#data16**: 16-bit constant.
- **bit**: Direct-accessed bit in Data RAM or SFR.
- **addr11**: 11-bit destination address used by ACALL and AJMP. The destination must be within the same 2 KB page of program memory as the first byte of the following instruction.
- **addr16**: 16-bit destination address used by LCALL and LJMP. The destination may be anywhere within the 8 KB program memory space.
- There is one unused opcode (0xA5) that performs the same function as NOP. All mnemonics copyrighted © Intel Corporation 1980.

## 10.4 CPU Core Registers

### 10.4.1 DPL: Data Pointer Low

Bit	7	6	5	4	3	2	1	0
Name	DPL							
Access	RW							
Reset	0x00							
SFR Address: 0x82								

Bit	Name	Reset	Access	Description
7:0	DPL	0x00	RW	<b>Data Pointer Low.</b> The DPL register is the low byte of the 16-bit DPTR. DPTR is used to access indirectly addressed flash memory or XRAM.

### 10.4.2 DPH: Data Pointer High

Bit	7	6	5	4	3	2	1	0
Name	DPH							
Access	RW							
Reset	0x00							
SFR Address: 0x83								

Bit	Name	Reset	Access	Description
7:0	DPH	0x00	RW	<b>Data Pointer High.</b> The DPH register is the high byte of the 16-bit DPTR. DPTR is used to access indirectly addressed flash memory or XRAM.

### 10.4.3 SP: Stack Pointer

Bit	7	6	5	4	3	2	1	0
Name	SP							
Access	RW							
Reset	0x07							
SFR Address: 0x81								

Bit	Name	Reset	Access	Description
7:0	SP	0x07	RW	<b>Stack Pointer.</b> The Stack Pointer holds the location of the top of the stack. The stack pointer is incremented before every PUSH operation. The SP register defaults to 0x07 after reset.

### 10.4.4 ACC: Accumulator

Bit	7	6	5	4	3	2	1	0
Name	ACC							
Access	RW							
Reset	0x00							
SFR Address: 0xE0 (bit-addressable)								

Bit	Name	Reset	Access	Description
7:0	ACC	0x00	RW	<b>Accumulator.</b> This register is the accumulator for arithmetic operations.

### 10.4.5 B: B Register

Bit	7	6	5	4	3	2	1	0
Name	B							
Access	RW							
Reset	0x00							
SFR Address: 0xF0 (bit-addressable)								

Bit	Name	Reset	Access	Description
7:0	B	0x00	RW	<b>B Register.</b> This register serves as a second accumulator for certain arithmetic operations.

### 10.4.6 PSW: Program Status Word

Bit	7	6	5	4	3	2	1	0
Name	CY	AC	F0	RS		OV	F1	PARITY
Access	RW	RW	RW	RW		RW	RW	R
Reset	0	0	0	0x0		0	0	0
SFR Address: 0xD0 (bit-addressable)								

Bit	Name	Reset	Access	Description															
7	CY	0	RW	<p><b>Carry Flag.</b></p> <p>This bit is set when the last arithmetic operation resulted in a carry (addition) or a borrow (subtraction). It is cleared to logic 0 by all other arithmetic operations.</p>															
6	AC	0	RW	<p><b>Auxiliary Carry Flag.</b></p> <p>This bit is set when the last arithmetic operation resulted in a carry into (addition) or a borrow from (subtraction) the high order nibble. It is cleared to logic 0 by all other arithmetic operations.</p>															
5	F0	0	RW	<p><b>User Flag 0.</b></p> <p>This is a bit-addressable, general purpose flag for use under firmware control.</p>

## 11. Port I/O, Crossbar, External Interrupts, and Port Match

### 11.1 Introduction

Digital and analog resources are externally available on the device's multi-purpose I/O pins. Port pins P0.0-P1.7 can be defined as general-purpose I/O (GPIO), assigned to one of the internal digital resources through the crossbar or dedicated channels, or assigned to an analog function. Port pins P2.0 and P2.1 can be used as GPIO. Additionally, the C2 Interface Data signal (C2D) is shared with P2.0.

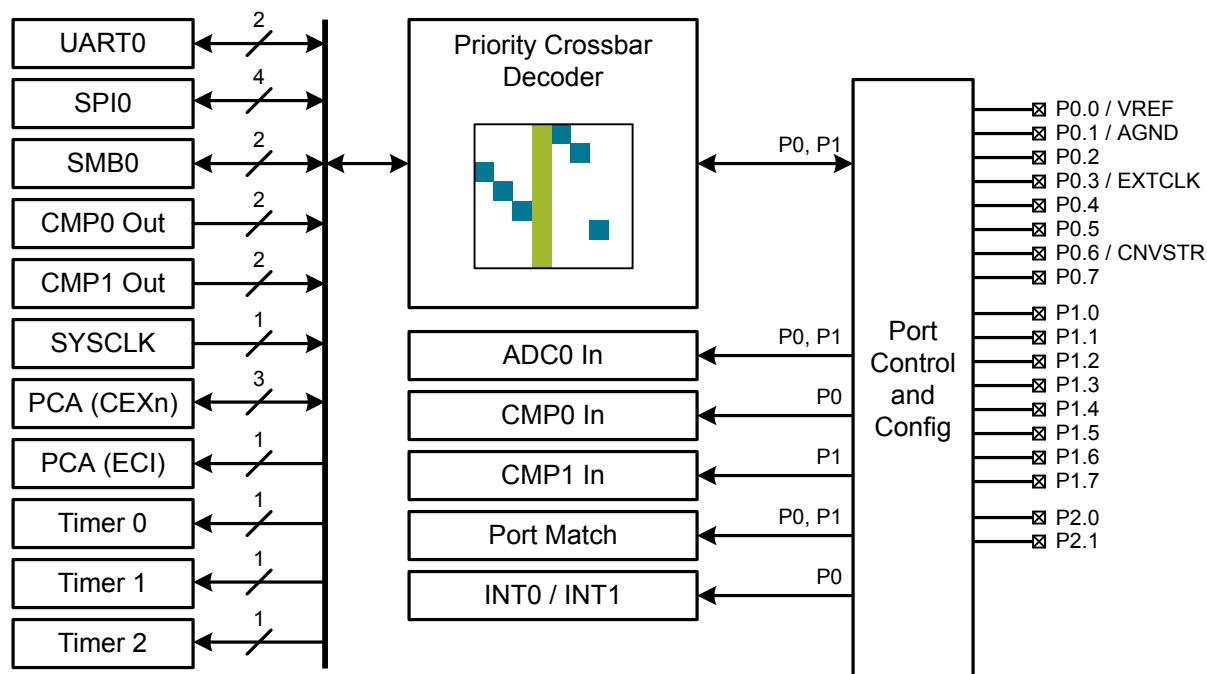

Figure 11.1. Port I/O Block Diagram

### 11.2 Features

- Up to 18 multi-functions I/O pins, supporting digital and analog functions.
- Flexible priority crossbar decoder for digital peripheral assignment.
- Two drive strength settings for each port.
- Two direct-pin interrupt sources with dedicated interrupt vectors (INT0 and INT1).
- Up to 16 direct-pin interrupt sources with shared interrupt vector (Port Match).

## 11.3 Functional Description

### 11.3.1 Port I/O Modes of Operation

Port pins are configured by firmware as digital or analog I/O using the special function registers. Port I/O initialization consists of the following general steps:

1. Select the input mode (analog or digital) for all port pins, using the Port Input Mode register (PnMDIN).
2. Select the output mode (open-drain or push-pull) for all port pins, using the Port Output Mode register (PnMDOUT).
3. Select any pins to be skipped by the I/O crossbar using the Port Skip registers (PnSKIP).
4. Assign port pins to desired peripherals.
5. Enable the crossbar (XBARE = 1).

A diagram of the port I/O cell is shown in the following figure.

Figure 11.2. Port I/O Cell Block Diagram

### Configuring Port Pins For Analog Modes

Any pins to be used for analog functions should be configured for analog mode. When a pin is configured for analog I/O, its weak pull-up, digital driver, and digital receiver are disabled. This saves power by eliminating crowbar current, and reduces noise on the analog input. Pins configured as digital inputs may still be used by analog peripherals; however this practice is not recommended. Port pins configured for analog functions will always read back a value of 0 in the corresponding Pn Port Latch register. To configure a pin as analog, the following steps should be taken:

1. Clear the bit associated with the pin in the PnMDIN register to 0. This selects analog mode for the pin.
2. Set the bit associated with the pin in the Pn register to 1.
3. Skip the bit associated with the pin in the PnSKIP register to ensure the crossbar does not attempt to assign a function to the pin.

## Configuring Port Pins For Digital Modes

Any pins to be used by digital peripherals or as GPIO should be configured as digital I/O (PnMDIN.n = 1). For digital I/O pins, one of two output modes (push-pull or open-drain) must be selected using the PnMDOUT registers.

Push-pull outputs (PnMDOUT.n = 1) drive the port pad to the supply rails based on the output logic value of the port pin. Open-drain outputs have the high side driver disabled; therefore, they only drive the port pad to the lowside rail when the output logic value is 0 and become high impedance inputs (both high low drivers turned off) when the output logic value is 1.

When a digital I/O cell is placed in the high impedance state, a weak pull-up transistor pulls the port pad to the high side rail to ensure the digital input is at a defined logic state. Weak pull-ups are disabled when the I/O cell is driven low to minimize power consumption, and they may be globally disabled by setting WEAKPUD to 1. The user should ensure that digital I/O are always internally or externally pulled or driven to a valid logic state to minimize power consumption. Port pins configured for digital I/O always read back the logic state of the port pad, regardless of the output logic value of the port pin.

To configure a pin as a digital input:

1. Set the bit associated with the pin in the PnMDIN register to 1. This selects digital mode for the pin.
2. Clear the bit associated with the pin in the PnMDOUT register to 0. This configures the pin as open-drain.
3. Set the bit associated with the pin in the Pn register to 1. This tells the output driver to “drive” logic high. Because the pin is configured as open-drain, the high-side driver is disabled, and the pin may be used as an input.

Open-drain outputs are configured exactly as digital inputs. The pin may be driven low by an assigned peripheral, or by writing 0 to the associated bit in the Pn register if the signal is a GPIO.

To configure a pin as a digital, push-pull output:

1. Set the bit associated with the pin in the PnMDIN register to 1. This selects digital mode for the pin.
2. Set the bit associated with the pin in the PnMDOUT register to 1. This configures the pin as push-pull.

If a digital pin is to be used as a general-purpose I/O, or with a digital function that is not part of the crossbar, the bit associated with the pin in the PnSKIP register can be set to 1 to ensure the crossbar does not attempt to assign a function to the pin. The crossbar must be enabled to use port pins as standard port I/O in output mode. Port output drivers of all I/O pins are disabled whenever the crossbar is disabled.

### 11.3.1.1 Port Drive Strength

Port drive strength can be controlled on a port-by-port basis using the PRTDRV register. Each port has a bit in PRTDRV to select the high or low drive strength setting for all pins on that port. By default, all ports are configured for high drive strength.

## 11.3.2 Analog and Digital Functions

### 11.3.2.1 Port I/O Analog Assignments

The following table displays the potential mapping of port I/O to each analog function.

**Table 11.1. Port I/O Assignment for Analog Functions**

Analog Function	Potentially Assignable Port Pins	SFR(s) Used For Assignment
ADC Input	P0.0 – P1.7	ADC0MX, PnSKIP, PnMDIN
Comparator 0 Input	P0.0 – P0.7 (QSOP24, QFN20) P0.0 – P0.5 (SOIC16)	CMP0MX, PnSKIP, PnMDIN
Comparator 1 Input	P1.0 – P1.7 (QSOP24) P1.0 – P1.6 (QFN20) P0.6 – P1.3 (SOIC16)	CMP1MX, PnSKIP, PnMDIN
Voltage Reference (VREF)	P0.0	REF0CN, PnSKIP, PnMDIN
Reference Ground (AGND)	P0.1	REF0CN, PnSKIP, PnMDIN

### 11.3.2.2 Port I/O Digital Assignments

The following table displays the potential mapping of port I/O to each digital function.

**Table 11.2. Port I/O Assignment for Digital Functions**

Digital Function	Potentially Assignable Port Pins	SFR(s) Used For Assignment
UART0, SPI0, SMB0, CP0, CP0A, CP1, CP1A, SYSCLOCK, PCA0 (CEX0-2 and ECI), T0, T1, T2	Any port pin available for assignment by the crossbar. This includes P0.0 – P1.7 pins which have their PnSKIP bit set to '0'. The crossbar will always assign UART0 pins to P0.4 and P0.5.	XBR0, XBR1, XBR2
External Interrupt 0, External Interrupt 1	P0.0 – P0.7	IT01CF
Conversion Start (CNVSTR)	P0.6	ADC0CN0
External Clock Input (EXTCLK)	P0.3	CLKSEL
Port Match	P0.0 – P1.7	P0MASK, P0MAT, P1MASK, P1MAT
Voltage Reference (VREF)	P0.0	REF0CN, PnSKIP, PnMDIN
Any pin used for GPIO	P0.0 – P2.1	P0SKIP, P1SKIP

### 11.3.3 Priority Crossbar Decoder

The priority crossbar decoder assigns a priority to each I/O function, starting at the top with UART0. The XBRn registers are used to control which crossbar resources are assigned to physical I/O port pins.

When a digital resource is selected, the least-significant unassigned port pin is assigned to that resource (excluding UART0, which is always assigned to dedicated pins). If a port pin is assigned, the crossbar skips that pin when assigning the next selected resource. Additionally, the PnSKIP registers allow software to skip port pins that are to be used for analog functions, dedicated digital functions, or GPIO. If a port pin is to be used by a function which is not assigned through the crossbar, its corresponding PnSKIP bit should be set to 1 in most cases. The crossbar skips these pins as if they were already assigned, and moves to the next unassigned pin.

It is possible for crossbar-assigned peripherals and dedicated functions to coexist on the same pin. For example, the port match function could be configured to watch for a falling edge on a UART RX line and generate an interrupt or wake up the device from a low-power state. However, if two functions share the same pin, the crossbar will have control over the output characteristics of that pin and the dedicated function will only have input access. Likewise, it is possible for firmware to read the logic state of any digital I/O pin assigned to a crossbar peripheral, but the output state cannot be directly modified.

Figure 11.3 Crossbar Priority Decoder Example Assignments on page 68 shows an example of the resulting pin assignments of the device with UART0 and SPI0 enabled and P0.3 skipped (P0SKIP = 0x08). UART0 is the highest priority and it will be assigned first. The UART0 pins can only appear at fixed locations (in this example, P0.4 and P0.5), so it occupies those pins. The next-highest enabled peripheral is SPI0. P0.0, P0.1 and P0.2 are free, so SPI0 takes these three pins. The fourth pin, NSS, is routed to P0.6 because P0.3 is skipped and P0.4 and P0.5 are already occupied by the UART. Any other pins on the device are available for use as general-purpose digital I/O or analog functions.

Port	P0								...	
	Pin Number	0	1	2	3	4	5	6		7
UART0-TX				█	█					
UART0-RX				█		█				
SPI0-SCK	█			█						
SPI0-MISO		█		█						
SPI0-MOSI			█	█						
SPI0-NSS				█			█			
...				█						
Pin Skip Settings	0	0	0	1	0	0	0	0	0	...
P0SKIP										
UART0 is assigned to fixed pins and has priority over SPI0. SPI0 is assigned to available, un-skipped pins.										
<div style="display: flex; gap: 10px;"> <div style="display: flex; align-items: center;"> <div style="width: 15px; height: 15px; background-color: #0070c0; margin-right: 5px;"></div> <span>Port pins assigned to the associated peripheral.</span> </div> <div style="display: flex; align-items: center;"> <div style="width: 15px; height: 15px; background-color: #92d050; margin-right: 5px;"></div> <span>P0.3 is skipped by setting P0SKIP.3 to 1.</span> </div> </div>										

Figure 11.3. Crossbar Priority Decoder Example Assignments

### 11.3.3.1 Crossbar Functional Map

[Figure 11.4 Full Crossbar Map on page 70](#) shows all of the potential peripheral-to-pin assignments available to the crossbar. Note that this does not mean any peripheral can always be assigned to the highlighted pins. The actual pin assignments are determined by the priority of the enabled peripherals.

Port	P0							P1							P2				
	0	1	2	3	4	5	6	7	0	1	2	3	4	5	6	7	0	1

Pins Not Available on Crossbar

The crossbar peripherals are assigned in priority order from top to bottom.

- These boxes represent Port pins which can potentially be assigned to a peripheral.
- Special Function Signals are not assigned by the crossbar. When these signals are enabled, the Crossbar should be manually configured to skip the corresponding port pins.
- Pins can be “skipped” by setting the corresponding bit in PnSKIP to 1.

\* NSS is only pinned out when the SPI is in 4-wire mode.

Figure 11.4. Full Crossbar Map

### 11.3.4 INT0 and INT1

Two direct-pin digital interrupt sources (INT0 and INT1) are included, which can be routed to port 0 pins. Additional I/O interrupts are available through the port match function. As is the case on a standard 8051 architecture, certain controls for these two interrupt sources are available in the Timer0/1 registers. Extensions to these controls which provide additional functionality are available in the IT01CF register. INT0 and INT1 are configurable as active high or low, edge- or level-sensitive. The IN0PL and IN1PL bits in the IT01CF register select active high or active low; the IT0 and IT1 bits in TCON select level- or edge-sensitive. The table below lists the possible configurations.

**Table 11.3. INT0/INT1 configuration**

IT0 or IT1	IN0PL or IN1PL	INT0 or INT1 Interrupt
1	0	Interrupt on falling edge
1	1	Interrupt on rising edge
0	0	Interrupt on low level
0	1	Interrupt on high level

INT0 and INT1 are assigned to port pins as defined in the IT01CF register. INT0 and INT1 port pin assignments are independent of any crossbar assignments, and may be assigned to pins used by crossbar peripherals. INT0 and INT1 will monitor their assigned port pins without disturbing the peripheral that was assigned the port pin via the crossbar. To assign a port pin only to INT0 and/or INT1, configure the crossbar to skip the selected pin(s).

IE0 and IE1 in the TCON register serve as the interrupt-pending flags for the INT0 and INT1 external interrupts, respectively. If an INT0 or INT1 external interrupt is configured as edge-sensitive, the corresponding interrupt pending flag is automatically cleared by the hardware when the CPU vectors to the ISR. When configured as level sensitive, the interrupt-pending flag remains logic 1 while the input is active as defined by the corresponding polarity bit (IN0PL or IN1PL); the flag remains logic 0 while the input is inactive. The external interrupt source must hold the input active until the interrupt request is recognized. It must then deactivate the interrupt request before execution of the ISR completes or another interrupt request will be generated.

### 11.3.5 Port Match

Port match functionality allows system events to be triggered by a logic value change on one or more port I/O pins. A software controlled value stored in the PnMATCH registers specifies the expected or normal logic values of the associated port pins (for example, P0MATCH.0 would correspond to P0.0). A port mismatch event occurs if the logic levels of the port's input pins no longer match the software controlled value. This allows software to be notified if a certain change or pattern occurs on the input pins regardless of the XBRn settings.

The PnMASK registers can be used to individually select which pins should be compared against the PnMATCH registers. A port mismatch event is generated if  $(Pn \ \& \ PnMASK) \neq (PnMATCH \ \& \ PnMASK)$  for all ports with a PnMAT and PnMASK register.

A port mismatch event may be used to generate an interrupt or wake the device from low power modes. See the interrupts and power options chapters for more details on interrupt and wake-up sources.

### 11.3.6 Direct Port I/O Access (Read/Write)

All port I/O are accessed through corresponding special function registers. When writing to a port, the value written to the SFR is latched to maintain the output data value at each pin. When reading, the logic levels of the port's input pins are returned regardless of the XBRn settings (i.e., even when the pin is assigned to another signal by the crossbar, the port register can always read its corresponding port I/O pin). The exception to this is the execution of the read-modify-write instructions that target a Port Latch register as the destination. The read-modify-write instructions when operating on a port SFR are the following: ANL, ORL, XRL, JBC, CPL, INC, DEC, DJNZ and MOV, CLR or SETB, when the destination is an individual bit in a port SFR. For these instructions, the value of the latch register (not the pin) is read, modified, and written back to the SFR.

## 11.4 Port I/O Control Registers

### 11.4.1 XBR0: Port I/O Crossbar 0

Bit	7	6	5	4	3	2	1	0
Name	SYSCKE	CP1AE	CP1E	CP0AE	CP0E	SMB0E	SPI0E	URT0E
Access	RW	RW	RW	RW	RW	RW	RW	RW

## 12. Analog-to-Digital Converter (ADC0)

### 12.1 Introduction

The ADC is a successive-approximation-register (SAR) ADC with 12-, 10-, and 8-bit modes, integrated track-and hold and a programmable window detector. The ADC is fully configurable under software control via several registers. The ADC may be configured to measure different signals using the analog multiplexer. The voltage reference for the ADC is selectable between internal and external reference sources.

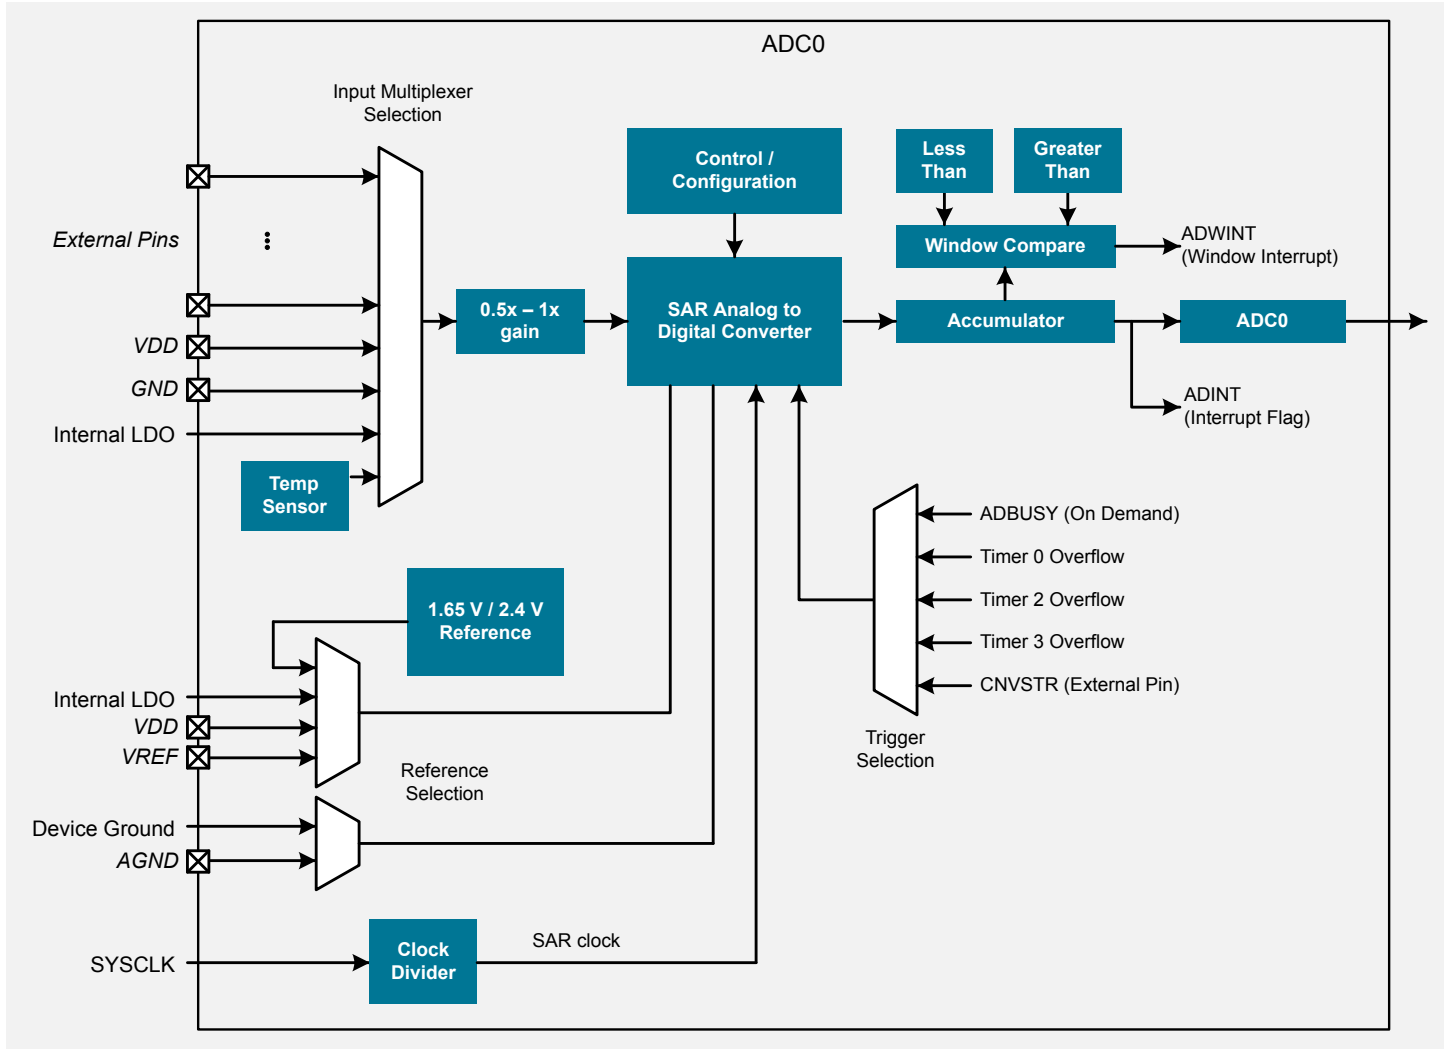

Figure 12.1. ADC Block Diagram

## 12.2 Features

- Up to 16 external inputs.
- Single-ended 12-bit and 10-bit modes.
- Supports an output update rate of 200 ksps samples per second in 12-bit mode or 800 ksps samples per second in 10-bit mode.
- Operation in low power modes at lower conversion speeds.
- Asynchronous hardware conversion trigger, selectable between software, external I/O and internal timer sources.
- Output data window comparator allows automatic range checking.
- Support for burst mode, which produces one set of accumulated data per conversion-start trigger with programmable power-on settling and tracking time.
- Conversion complete and window compare interrupts supported.
- Flexible output data formatting.
- Includes an internal fast-settling reference with two levels (1.65 V and 2.4 V) and support for external reference and signal ground.
- Integrated temperature sensor.

## 12.3 Functional Description

### 12.3.1 Clocking

The ADC is clocked by an adjustable conversion clock (SARCLK). SARCLK is a divided version of the selected system clock when burst mode is disabled (ADBMEN = 0), or a divided version of the HFOSC0 oscillator when burst mode is enabled (ADBMEN = 1). The clock divide value is determined by the ADOSC field. In most applications, SARCLK should be adjusted to operate as fast as possible, without exceeding the maximum electrical specifications. The SARCLK does not directly determine sampling times or sampling rates.

### 12.3.2 Voltage Reference Options

The voltage reference multiplexer is configurable to use a number of different internal and external reference sources. The ground reference mux allows the ground reference for ADC0 to be selected between the ground pin (GND) or a port pin dedicated to analog ground (AGND). The voltage and ground reference options are configured using the REF0CN register. The REFSL field selects between the different reference options, while GNDSL configures the ground connection.

#### 12.3.2.1 Internal Voltage Reference

The high-speed internal reference offers two programmable voltage levels, and is self-contained and stabilized. It is not routed to an external pin and requires no external decoupling. When selected, the internal reference will be automatically enabled/disabled on an as-needed basis by the ADC. The reference can be set to one of two voltage values: 1.65 V or 2.4 V, depending on the value of the IREFLVL bit. The electrical specifications tables detail SAR clock and throughput limitations for each reference source.

#### 12.3.2.2 Supply or LDO Voltage Reference

For applications with a non-varying power supply voltage, using the power supply as the voltage reference can provide the ADC with added dynamic range at the cost of reduced power supply noise rejection. Additionally, the internal 1.8 V LDO supply to the core may be used as a reference. Neither of these reference sources are routed to the VREF pin, and do not require additional external decoupling.

#### 12.3.2.3 External Voltage Reference

An external reference may be applied to the VREF pin. Bypass capacitors should be added as recommended by the manufacturer of the external voltage reference. If the manufacturer does not provide recommendations, a 4.7  $\mu\text{F}$  in parallel with a 0.1  $\mu\text{F}$  capacitor is recommended.

**Note:** The VREF pin is a multi-function GPIO pin. When using an external voltage reference, VREF should be configured as an analog input and skipped by the crossbar.

### 12.3.2.4 Ground Reference

To prevent ground noise generated by switching digital logic from affecting sensitive analog measurements, a separate analog ground reference option is available. When enabled, the ground reference for the ADC during both the tracking/sampling and the conversion periods is taken from the AGND pin. Any external sensors sampled by the ADC should be referenced to the AGND pin. If an external voltage reference is used, the AGND pin should be connected to the ground of the external reference and its associated decoupling capacitor. The separate analog ground reference option is enabled by setting GNDSL to 1. Note that when sampling the internal temperature sensor, the internal chip ground is always used for the sampling operation, regardless of the setting of the GNDSL bit. Similarly, whenever the internal high-speed reference is selected, the internal chip ground is always used during the conversion period, regardless of the setting of the GNDSL bit.

**Note:** The AGND pin is a multi-function GPIO pin. When using AGND as the ground reference to the ADC, AGND should be configured as an analog input and skipped by the crossbar.

### 12.3.3 Input Selection

The ADC has an analog multiplexer which allows selection of external pins, the on-chip temperature sensor, the internal regulated supply, the VDD supply, or GND. ADC input channels are selected using the ADC0MX register.

**Note:** Any port pins selected as ADC inputs should be configured as analog inputs in their associated port configuration register, and configured to be skipped by the crossbar.

#### 12.3.3.1 Multiplexer Channel Selection

**Table 12.1. ADC0 Input Multiplexer Channels**

ADC0MX setting	Signal Name	Enumeration Name	QSOP24 Pin Name	QFN20 Pin Name	SOIC16 Pin Name
00000	ADC0.0	ADC0P0	P0.0	P0.0	P0.0
00001	ADC0.1	ADC0P1	P0.1	P0.1	P0.1
00010	ADC0.2	ADC0P2	P0.2	P0.2	P0.2
00011	ADC0.3	ADC0P3	P0.3	P0.3	P0.3
00100	ADC0.4	ADC0P4	P0.4	P0.4	P0.4
00101	ADC0.5	ADC0P5	P0.5	P0.5	P0.5
00110	ADC0.6	ADC0P6	P0.6	P0.6	P0.6
00111	ADC0.7	ADC0P7	P0.7	P0.7	P0.7
01000	ADC0.8	ADC0P8	P1.0	P1.0	P1.0
01001	ADC0.9	ADC0P9	P1.1	P1.1	P1.1
01010	ADC0.10	ADC0P10	P1.2	P1.2	P1.2
01011	ADC0.11	ADC0P11	P1.3	P1.3	P1.3
01100	ADC0.12	ADC0P12	P1.4	P1.4	Reserved
01101	ADC0.13	ADC0P13	P1.5	P1.5	Reserved
01110	ADC0.14	ADC0P14	P1.6	P1.6	Reserved
01111	ADC0.15	ADC0P15	P1.7	Reserved	Reserved
10000	ADC0.16	TEMP	Internal Temperature Sensor		
10001	ADC0.17	LDO_OUT	Internal 1.8 V LDO Output		
10010	ADC0.18	VDD	VDD Supply Pin		
10011	ADC0.19	GND	GND Supply Pin		
10100-11111	ADC0.20-ADC0.31	NONE	No connection		

### 12.3.4 Gain Setting

The ADC has gain settings of 1x and 0.5x. In 1x mode, the full scale reading of the ADC is determined directly by VREF. In 0.5x mode, the full-scale reading of the ADC occurs when the input voltage is VREF x 2. The 0.5x gain setting can be useful to obtain a higher input voltage range when using a small VREF voltage, or to measure input voltages that are between VREF and the supply voltage. Gain settings for the ADC are controlled by the ADGN bit in register ADC0CF. Note that even with a gain setting of 0.5, voltages above the supply rail cannot be measured directly by the ADC.

### 12.3.5 Initiating Conversions

A conversion can be initiated in many ways, depending on the programmed state of the ADCM bitfield. Conversions may be initiated by one of the following:

1. Software-triggered—Writing a 1 to the ADBUSY bit initiates the conversion.
2. Hardware-triggered—An automatic internal event such as a timer overflow initiates the conversion.
3. External pin-triggered—A rising edge on the CNVSTR input signal initiates the conversion.

Writing a 1 to ADBUSY provides software control of ADC0 whereby conversions are performed "on-demand". All other trigger sources occur autonomous to code execution. When the conversion is complete, the ADC posts the result to its output register and sets the ADC interrupt flag (ADINT). ADINT may be used to trigger a system interrupts, if enabled, or polled by firmware.

During a conversion, the ADBUSY bit is set to logic 1 and reset to logic 0 when the conversion is complete. However, the ADBUSY bit should not be used to poll for ADC conversion completion. The ADC0 interrupt flag (ADINT) should be used instead of the ADBUSY bit. Converted data is available in the ADC0 data registers, ADC0H:ADC0L, when the conversion is complete.

**Note:** The CNVSTR pin is a multi-function GPIO pin. When the CNVSTR input is used as the ADC conversion source, the associated port pin should be skipped in the crossbar settings.

### 12.3.6 Input Tracking

Each ADC conversion must be preceded by a minimum tracking time to allow the voltage on the sampling capacitor to settle, and for the converted result to be accurate.

## Settling Time Requirements

The absolute minimum tracking time is given in the electrical specifications tables. It may be necessary to track for longer than the minimum tracking time specification, depending on the application. For example, if the ADC input is presented with a large series impedance, it will take longer for the sampling cap to settle on the final value during the tracking phase. The exact amount of tracking time required is a function of all series impedance (including the internal mux impedance and any external impedance sources), the sampling capacitance, and the desired accuracy.

Note: The value of  $C_{SAMPLE}$  depends on the PGA gain. See the electrical specifications for details.

**Figure 12.2. ADC Equivalent Input Circuit**

The required ADC0 settling time for a given settling accuracy (SA) may be approximated as follows:

$$t = \ln\left(\frac{2^n}{SA}\right) \times R_{TOTAL} \times C_{SAMPLE}$$

Where: SA is the settling accuracy, given as a fraction of an LSB (for example, 0.25 to settle within 1/4 LSB)

t is the required settling time in seconds

$R_{TOTAL}$  is the sum of the ADC mux resistance and any external source resistance.

$C_{SAMPLE}$  is the size of the ADC sampling capacitor.

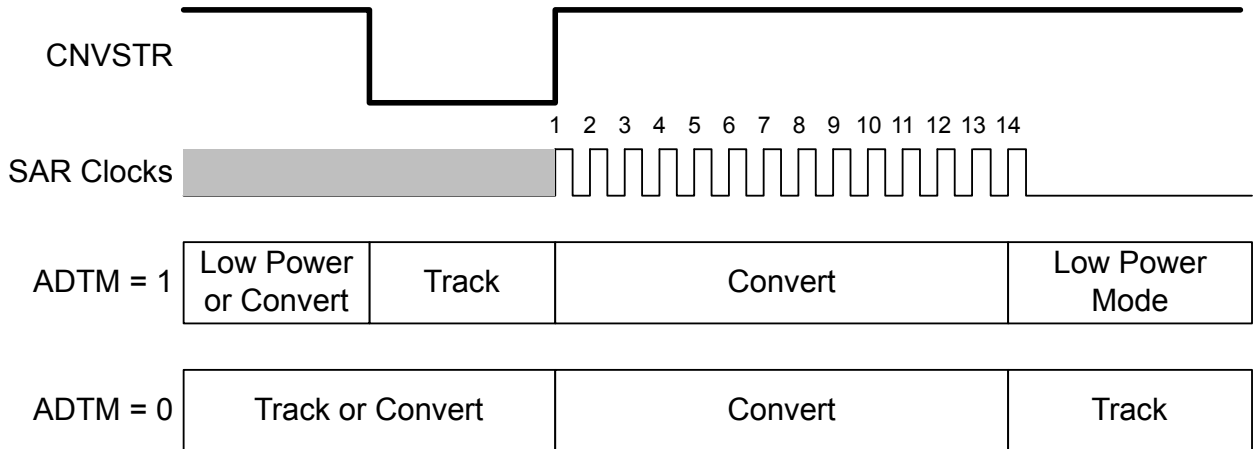

n is the ADC resolution in bits.

When measuring any internal source,  $R_{TOTAL}$  reduces to  $R_{MUX}$ . See the electrical specification tables in the datasheet for ADC minimum settling time requirements as well as the mux impedance and sampling capacitor values.

### Configuring the Tracking Time

When burst mode is disabled, the ADTM bit controls the ADC track-and-hold mode. In its default state the ADC input is continuously tracked, except when a conversion is in progress. A conversion will begin immediately when the start-of-conversion trigger occurs. When the ADTM bit is logic 1, each conversion is preceded by a tracking period of 4 SAR clocks (after the start-of-conversion signal) for any internal conversion trigger source. When the CNVSTR signal is used to initiate conversions with ADTM set to 1, ADC0 tracks only when CNVSTR is low; conversion begins on the rising edge of CNVSTR. Setting ADTM to 1 is primarily useful when AMUX settings are frequently changed and conversions are started using the ADBUSY bit.

#### A. ADC0 Timing for External Trigger Source

#### B. ADC0 Timing for Internal Trigger Source

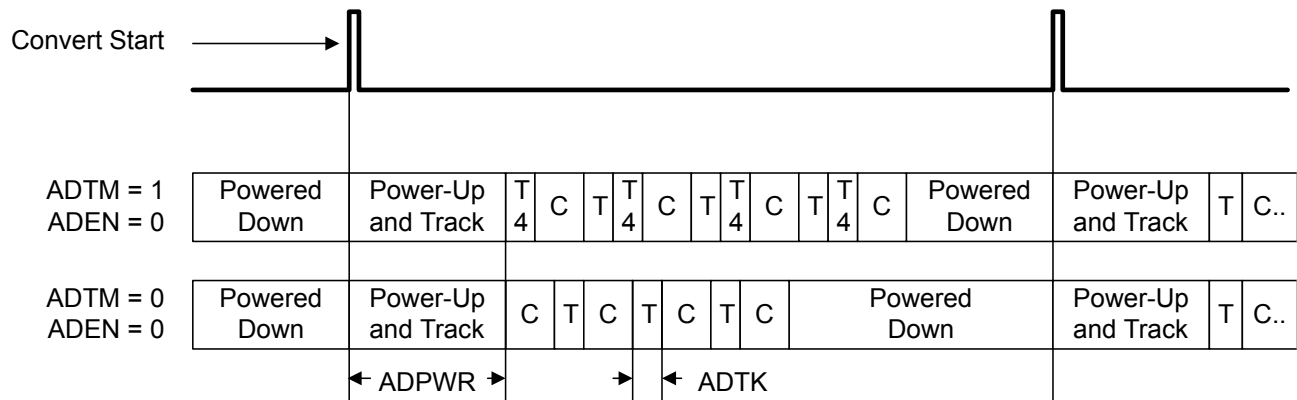

Figure 12.3. Track and Conversion Example Timing (Normal, Non-Burst Operation)

When burst mode is enabled, additional tracking times may need to be specified. Because burst mode may power the ADC on from an unpowered state and take multiple conversions for each start-of-conversion source, two additional timing fields are provided. If the ADC is powered down when the burst sequence begins, it will automatically power up and wait for the time specified in the ADPWR bit field. If the ADC is already powered on, tracking depends solely on ADTM for the first conversion. The ADTK field determines the amount of tracking time given to any subsequent samples in burst mode—essentially, ADTK specifies how long the ADC will wait between burst-mode conversions. If ADTM is set, an additional 4 SAR clocks will be added to the tracking phase of all conversions in burst mode.

Figure 12.4. Burst Mode Timing

T = Tracking set by ADTK  
 T4 = Tracking set by ADTM (4 SAR clocks)  
 C = Converting

### 12.3.7 Burst Mode

Burst mode is a power saving feature that allows the ADC to remain in a low power state between conversions. When burst mode is enabled, the ADC wakes from a low power state, accumulates 1, 4, 8, 16, 32, or 64 samples using the internal low-power high-frequency oscillator, then re-enters a low power state. Since the burst mode clock is independent of the system clock, the ADC can perform multiple conversions then enter a low power state within a single system clock cycle, even if the system clock is running from a slow oscillator.

**Note:** When using burst mode, care must be taken to issue a convert start signal no faster than once every four SYSCLK periods. This includes external convert start signals. The ADC will ignore convert start signals which arrive before a burst is finished.

Burst mode is enabled by setting ADBMEN to logic 1. When in burst mode, ADEN controls the ADC idle power state (i.e., the state the ADC enters when not tracking or performing conversions). If ADEN is set to logic 0, the ADC is powered down after each burst. If ADEN is set to logic 1, the ADC remains enabled after each burst. On each convert start signal, the ADC is awakened from its idle power state. If the ADC is powered down, it will automatically power up and wait for the amount of time programmed to the ADPWR bits before performing a conversion. Otherwise, the ADC will start tracking and converting immediately.

When burst mode is enabled, a single convert start will initiate a number of conversions equal to the repeat count. When burst mode is disabled, a convert start is required to initiate each conversion. In both modes, the ADC end of conversion interrupt flag (ADINT) will be set after “repeat count” conversions have been accumulated. Similarly, the window comparator will not compare the result to the greater-than and less-than registers until “repeat count” conversions have been accumulated.

### 12.3.8 8-Bit Mode

Setting the AD8BE bit to 1 will put the ADC in 8-bit mode. In 8-bit mode, only the 8 MSBs of data are converted, allowing the conversion to be completed in fewer SAR clock cycles than a 10-bit conversion. The two LSBs of a conversion are always 00 in this mode, and the ADC0L register will always read back 0x00.

### 12.3.9 12-Bit Mode

When configured for 12-bit conversions, the ADC performs four 10-bit conversions using four different reference voltages and combines the results into a single 12-bit value. Unlike simple averaging techniques, this method provides true 12-bit resolution of ac or dc input signals without depending on noise to provide dithering. The converter also employs a hardware dynamic element matching algorithm that reconfigures the largest elements of the internal DAC for each of the four 10-bit conversions. This reconfiguration cancels any matching errors and enables the converter to achieve 12-bit linearity performance to go along with its 12-bit resolution.

The 12-bit mode is enabled by setting the AD12BE bit in register ADC0AC to logic 1 and configuring the ADC in burst mode (ADBMEN = 1) for four or more conversions. The conversion can be initiated using any of the conversion start sources, and the 12-bit result will appear in the ADC0H and ADC0L registers. Since the 12-bit result is formed from a combination of four 10-bit results, the maximum output value is  $4 \times (1023) = 4092$ , rather than the max value of  $(2^{12} - 1) = 4095$  that is produced by a traditional 12-bit converter. To further increase resolution, the burst mode repeat value may be configured to any multiple of four conversions. For example, if a repeat value of 16 is selected, the ADC0 output will be a 14-bit number (sum of four 12-bit numbers) with 13 effective bits of resolution.

The AD12SM bit in register ADC0TK controls when the ADC will track and sample the input signal. When AD12SM is set to 1, the selected input signal will be tracked before the first conversion of a set and held internally during all four conversions. When AD12SM is cleared to 0, the ADC will track and sample the selected input before each of the four conversions in a set. When maximum throughput (180-200 ksps) is needed, it is recommended that AD12SM be set to 1 and ADTK to 0x3F, and that the ADC be placed in always-on mode (ADEN = 1). For sample rates under 180 ksps, or when accumulating multiple samples, AD12SM should normally be cleared to 0, and ADTK should be configured to provide the appropriate settling time for the subsequent conversions.

### 12.3.10 Output Formatting

The registers ADC0H and ADC0L contain the high and low bytes of the output conversion code from the ADC at the completion of each conversion. Data can be right-justified or left-justified, depending on the setting of the ADSJST field. When the repeat count is set to 1 in 10-bit mode, conversion codes are represented as 10-bit unsigned integers. Inputs are measured from 0 to VREF x 1023/1024. Example codes are shown below for both right-justified and left-justified data. Unused bits in the ADC0H and ADC0L registers are set to 0.

**Table 12.2. 10-Bit Output Code Example**

Input Voltage	Right-Justified (ADSJST = 000)	Left-Justified (ADSJST = 100)
	ADC0H:L	ADC0H:L
VREF x 1023/1024	0x03FF	0xFFC0
VREF x 512/1024	0x0200	0x8000
VREF x 256/1024	0x0100	0x4000
0	0x0000	0x0000

When the repeat count is greater than 1, the output conversion code represents the accumulated result of the conversions performed and is updated after the last conversion in the series is finished. Sets of 4, 8, 16, 32, or 64 consecutive samples can be accumulated and represented in unsigned integer format. The repeat count can be selected using the ADRPT bit field. When a repeat count is higher than 1, the ADC output must be right-justified (ADSJST = 0xx); unused bits in the ADC0H and ADC0L registers are set to 0. The example below shows the right-justified result for various input voltages and repeat counts. Notice that accumulating 2n samples is equivalent to left-shifting by n bit positions when all samples returned from the ADC have the same value.

**Table 12.3. Effects of ADRPT on Output Code**

Input Voltage	Repeat Count = 4	Repeat Count = 16	Repeat Count = 64
VREF x 1023/1024	0x0FFC	0x3FF0	0xFFC0
VREF x 512/1024	0x0800	0x2000	0x8000
VREF x 511/1024	0x07FC	0x1FF0	0x7FC0
0	0x0000	0x0000	0x0000

Additionally, the ADSJST bit field can be used to format the contents of the 16-bit accumulator. The accumulated result can be shifted right by 1, 2, or 3 bit positions. Based on the principles of oversampling and averaging, the effective ADC resolution increases by 1 bit each time the oversampling rate is increased by a factor of 4. The example below shows how to increase the effective ADC resolution by 1, 2, and 3 bits to obtain an effective ADC resolution of 11-bit, 12-bit, or 13-bit respectively without CPU intervention.

**Table 12.4. Using ADSJST for Output Formatting**

Input Voltage	Repeat Count = 4	Repeat Count = 16	Repeat Count = 64
	Shift Right = 1 11-Bit Result	Shift Right = 2 12-Bit Result	Shift Right = 3 12-Bit Result
VREF x 1023/1024	0x07F7	0x0FFC	0x1FF8
VREF x 512/1024	0x0400	0x0800	0x1000
VREF x 511/1024	0x03FE	0x04FC	0x0FF8
0	0x0000	0x0000	0x0000

### 12.3.11 Power Considerations

The ADC has several power-saving features which can help the user optimize power consumption according to the needs of the application. The most efficient way to use the ADC for slower sample rates is by using burst mode. Burst mode dynamically controls power to the ADC and (if used) the internal voltage reference. By completely powering off these circuits when the ADC is not tracking or converting, the average supply current required for lower sampling rates is reduced significantly.

The ADC also provides low power options that allow reduction in operating current when operating at low SAR clock frequencies or with longer tracking times. The internal common-mode buffer can be configured for low power mode by setting the ADLPM bit in ADC0PWR to 1. Two other fields in the ADC0PWR register (ADBIAS and ADMXLP) may be used together to adjust the power consumed by the ADC and its multiplexer and reference buffers, respectively. In general, these options are used together, when operating with a SAR conversion clock frequency of 4 MHz.

**Table 12.5. ADC Optimal Power Configuration (8- and 10-bit Mode)**

Required Throughput	Reference Source	Mode Configuration	SAR Clock Speed	Other Register Field Settings
325-800 ksps	Any	Always-On (ADEN = 1 ADBMEN = 0)	12.25 MHz (ADSC = 1)	ADC0PWR = 0x40 ADC0TK = N/A ADRPT = 0
0-325 ksps	External	Burst Mode (ADEN = 0 ADBMEN = 1)	12.25 MHz (ADSC = 1)	ADC0PWR = 0x44 ADC0TK = 0x3A ADRPT = 0
250-325 ksps	Internal	Burst Mode (ADEN = 0 ADBMEN = 1)	12.25 MHz (ADSC = 1)	ADC0PWR = 0x44 ADC0TK = 0x3A ADRPT = 0
200-250 ksps	Internal	Burst Mode (ADEN = 0 ADBMEN = 1)	4.08 MHz (ADSC = 5)	ADC0PWR = 0xF0 ADC0TK = N/A ADRPT = 0
0-200 ksps	Internal	Burst Mode (ADEN = 0 ADBMEN = 1)	4.08 MHz (ADSC = 5)	ADC0PWR = 0xF4 ADC0TK = 0x34 ADRPT = 0

**Notes:**

1. For always-on configuration, ADSC settings assume SYSCLK is the internal 24.5 MHz high-frequency oscillator. Adjust ADSC as needed if using a different source for SYSCLK.
2. ADRPT reflects the minimum setting for this bit field. When using the ADC in Burst Mode, up to 64 samples may be auto-accumulated per conversion start by adjusting ADRPT.

**Table 12.6. ADC Optimal Power Configuration (12-bit Mode)**

Required Throughput	Reference Source	Mode Configuration	SAR Clock Speed	Other Register Field Settings
180-200 ksps	Any	Always-On + Burst Mode (ADEN = 1 ADBMEN = 1)	12.25 MHz (ADSC = 1)	ADC0PWR = 0x40 ADC0TK = 0xBF ADRPT = 1

Required Throughput	Reference Source	Mode Configuration	SAR Clock Speed	Other Register Field Settings
125-180 ksps	Any	Always-On + Burst Mode (ADEN = 1 ADBMEN = 1)	12.25 MHz (ADSC = 1)	ADC0PWR = 0x40 ADC0TK = 0x3A ADRPT = 1
0-125 ksps	External	Burst Mode (ADEN = 0 ADBMEN = 1)	12.25 MHz (ADSC = 1)	ADC0PWR = 0x44 ADC0TK = 0x3A ADRPT = 1
50-125 ksps	Internal	Burst Mode (ADEN = 0 ADBMEN = 1)	12.25 MHz (ADSC = 1)	ADC0PWR = 0x44 ADC0TK = 0x3A ADRPT = 1
0-50 ksps	Internal	Burst Mode (ADEN = 0 ADBMEN = 1)	4.08 MHz (ADSC = 5)	ADC0PWR = 0xF4 ADC0TK = 0x34 ADRPT = 1

Notes:

- ADRPT reflects the minimum setting for this bit field. When using the ADC in burst mode, up to 64 samples may be auto-accumulated per conversion trigger by adjusting ADRPT.

For applications where burst mode is used to automatically accumulate multiple results, additional supply current savings can be realized. The length of time the ADC is active during each burst contains power-up time at the beginning of the burst as well as the conversion time required for each conversion in the burst. The power-on time is only required at the beginning of each burst. When compared with single-sample bursts to collect the same number of conversions, multi-sample bursts will consume significantly less power. For example, performing an eight-cycle burst of 10-bit conversions consumes about 61% of the power required to perform those same eight samples in single-cycle bursts. For 12-bit conversions, an eight-cycle burst results in about 85% of the equivalent single-cycle bursts. See the electrical characteristics tables for details on power consumption and the maximum clock frequencies allowed in each mode.

Figure 12.5. Burst Mode Accumulation Power Savings

### 12.3.12 Window Comparator

The ADC's programmable window detector continuously compares the ADC output registers to user-programmed limits, and notifies the system when a desired condition is detected. This is especially effective in an interrupt driven system, saving code space and CPU bandwidth while delivering faster system response times. The window detector interrupt flag (ADWINT) can also be used in polled mode. The ADC Greater-Than (ADC0GTH, ADC0GTL) and Less-Than (ADC0LTH, ADC0LTL) registers hold the comparison values. The window detector flag can be programmed to indicate when measured data is inside or outside of the user-programmed limits, depending on the contents of the ADC0GT and ADC0LT registers. The following tables show how the ADC0GT and ADC0LT registers may be configured to set the ADWINT flag when the ADC output code is above, below, between, or outside of specific values.

**Table 12.7. ADC Window Comparator Example (Above 0x0080)**

Comparison Register Settings	Output Code (ADC0H:L)	ADWINT Effects
	0x03FF	ADWINT = 1
	...	
	0x0081	
ADC0GTH:L = 0x0080	0x0080	ADWINT Not Affected
	0x007F	
	...	
	0x0001	
	ADC0LTH:L = 0x0000	0x0000

**Table 12.8. ADC Window Comparator Example (Below 0x0040)**

Comparison Register Settings	Output Code (ADC0H:L)	ADWINT Effects

### 12.3.13 Temperature Sensor

An on-chip analog temperature sensor is available to the ADC multiplexer input. To use the ADC to measure the temperature sensor, the ADC mux channel should select the temperature sensor. The temperature sensor transfer function is shown in [Figure 12.6 Temperature Sensor Transfer Function on page 105](#). The output voltage ( $V_{TEMP}$ ) is the positive ADC input when the ADC multiplexer is set correctly. The TEMPE bit in register REF0CN enables/ disables the temperature sensor. While disabled, the temperature sensor defaults to a high impedance state and any ADC measurements performed on the sensor will result in meaningless data. Refer to the electrical specification tables for the slope and offset parameters of the temperature sensor.

Figure 12.6. Temperature Sensor Transfer Function

#### 12.3.13.1 Temperature Sensor Calibration

The uncalibrated temperature sensor output is extremely linear and suitable for relative temperature measurements. For absolute temperature measurements, offset and/or gain calibration is recommended. Typically a 1-point (offset) calibration includes the following steps:

1. Control/measure the ambient temperature (this temperature must be known).
2. Power the device, and delay for a few seconds to allow for self-heating.
3. Perform an ADC conversion with the temperature sensor selected as the ADC input.
4. Calculate the offset characteristics, and store this value in non-volatile memory for use with subsequent temperature sensor measurements.

## 12.4 ADC0 Control Registers

### 12.4.1 ADC0CN0: ADC0 Control 0

Bit	7	6	5	4	3	2	1	0
Name	ADEN	ADBMEN	ADINT	ADBUSY	ADWINT	ADCM		
Access	RW	RW	RW	RW	RW	RW		
Reset	0	0	0	0	0	0x0		

SFR Address: 0xE8 (bit-addressable)

Bit	Name	Reset	Access	Description
7	ADEN	0	RW	<b>ADC Enable.</b>
	Value	Name	Description	
	0	DISABLED	Disable ADC0 (low-power shutdown).	
	1	ENABLED	Enable ADC0 (active and ready for data conversions).	
6	ADBMEN	0	RW	<b>Burst Mode Enable.</b>
	Value	Name	Description	
	0	BURST_DISABLED	Disable ADC0 burst mode.	
	1	BURST_ENABLED	Enable ADC0 burst mode.	
5	ADINT	0	RW	<b>Conversion Complete Interrupt Flag.</b> Set by hardware upon completion of a data conversion (ADBMEN=0), or a burst of conversions (ADBMEN=1). Can trigger an interrupt. Must be cleared by firmware.
4	ADBUSY	0	RW	<b>ADC Busy.</b> Writing 1 to this bit initiates an ADC conversion when ADCM = 000. This bit should not be polled to indicate when a conversion is complete. Instead, the ADINT bit should be used when polling for conversion completion.
3	ADWINT	0	RW	<b>Window Compare Interrupt Flag.</b> Set by hardware when the contents of ADC0H:ADC0L fall within the window specified by ADC0GTH:ADC0GTL and ADC0LTH:ADC0LTL. Can trigger an interrupt. Must be cleared by firmware.
2:0	ADCM	0x0	RW	<b>Start of Conversion Mode Select.</b> Specifies the ADC0 start of conversion source. All remaining bit combinations are reserved.
	Value	Name	Description	
	0x0	ADBUSY	ADC0 conversion initiated on write of 1 to ADBUSY.	
	0x1	TIMER0	ADC0 conversion initiated on overflow of Timer 0.	
	0x2	TIMER2	ADC0 conversion initiated on overflow of Timer 2.	
	0x3	TIMER3	ADC0 conversion initiated on overflow of Timer 3.	
	0x4	CNVSTR	ADC0 conversion initiated on rising edge of CNVSTR.	

### 12.4.2 ADC0CN1: ADC0 Control 1

Bit	7	6	5	4	3	2	1	0
Name	Reserved							ADCMBE
Access	R							RW
Reset	0x00							0
SFR Address: 0xB2								

Bit	Name	Reset	Access	Description
7:1	<i>Reserved</i>	<i>Must write reset value.</i>		
0	ADCMBE	0	RW	<b>Common Mode Buffer Enable.</b>
	Value	Name		Description
	0	CM_BUFFER_DISABLED		Disable the common mode buffer. This setting should be used only if the tracking time of the signal is greater than 1.5 us.
	1	CM_BUFFER_ENABLED		Enable the common mode buffer. This setting should be used in most cases, and will give the best dynamic ADC performance. The common mode buffer must be enabled if signal tracking time is less than or equal to 1.5 us.

### 12.4.3 ADC0CF: ADC0 Configuration

Bit	7	6	5	4	3	2	1	0
Name	ADSC					AD8BE	ADTM	ADGN
Access	RW					RW	RW	RW
Reset	0x1F					0	0	0
SFR Address: 0xBC								

Bit	Name	Reset	Access	Description									
7:3	ADSC	0x1F	RW	<b>SAR Clock Divider.</b> This field sets the ADC clock divider value. It should be configured to be as close to the maximum SAR clock speed as the datasheet will allow. The SAR clock frequency is given by the following equation: $F_{clk_{sar}} = (F_{adc_{clk}}) / (ADSC + 1)$ $F_{ADCCLK}$ is equal to the selected SYSCLK when ADBMEN is 0 and the high-frequency oscillator when ADBMEN is 1.									
2	AD8BE	0	RW	<b>8-Bit Mode Enable.</b> <table border="1"> <thead> <tr> <th>Value</th> <th>Name</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>NORMAL</td> <td>ADC0 operates in 10-bit or 12-bit mode (normal operation).</td> </tr> <tr> <td>1</td> <td>8_BIT</td> <td>ADC0 operates in 8-bit mode.</td> </tr> </tbody> </table>	Value	Name	Description	0	NORMAL	ADC0 operates in 10-bit or 12-bit mode (normal operation).	1	8_BIT	ADC0 operates in 8-bit mode.
Value	Name	Description											
0	NORMAL	ADC0 operates in 10-bit or 12-bit mode (normal operation).											
1	8_BIT	ADC0 operates in 8-bit mode.											
1	ADTM	0	RW	<b>Track Mode.</b> Selects between Normal or Delayed Tracking Modes. <table border="1"> <thead> <tr> <th>Value</th> <th>Name</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>TRACK_NORMAL</td> <td>Normal Track Mode. When ADC0 is enabled, conversion begins immediately following the start-of-conversion signal.</td> </tr> <tr> <td>1</td> <td>TRACK_DELAYED</td> <td>Delayed Track Mode. When ADC0 is enabled, conversion begins 4 SAR clock cycles following the start-of-conversion signal. The ADC is allowed to track during this time.</td> </tr> </tbody> </table>	Value	Name	Description	0	TRACK_NORMAL	Normal Track Mode. When ADC0 is enabled, conversion begins immediately following the start-of-conversion signal.	1	TRACK_DELAYED	Delayed Track Mode. When ADC0 is enabled, conversion begins 4 SAR clock cycles following the start-of-conversion signal. The ADC is allowed to track during this time.
Value	Name	Description											
0	TRACK_NORMAL	Normal Track Mode. When ADC0 is enabled, conversion begins immediately following the start-of-conversion signal.											
1	TRACK_DELAYED	Delayed Track Mode. When ADC0 is enabled, conversion begins 4 SAR clock cycles following the start-of-conversion signal. The ADC is allowed to track during this time.											
0	ADGN	0	RW	<b>Gain Control.</b> <table border="1"> <thead> <tr> <th>Value</th> <th>Name</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>GAIN_0P5</td> <td>The on-chip PGA gain is 0.5.</td> </tr> <tr> <td>1</td> <td>GAIN_1</td> <td>The on-chip PGA gain is 1.</td> </tr> </tbody> </table>	Value	Name	Description	0	GAIN_0P5	The on-chip PGA gain is 0.5.	1	GAIN_1	The on-chip PGA gain is 1.
Value	Name	Description											
0	GAIN_0P5	The on-chip PGA gain is 0.5.											
1	GAIN_1	The on-chip PGA gain is 1.											

#### 12.4.4 ADC0AC: ADC0 Accumulator Configuration

Bit	7	6	5	4	3	2	1	0
Name	AD12BE	ADAE	ADSJST			ADRPT		
Access	RW	RW	RW			RW		
Reset	0	0	0x0			0x0		
SFR Address: 0xB3								

Bit	Name	Reset	Access	Description
7	AD12BE	0	RW	<b>12-Bit Mode Enable.</b> Enables 12-bit mode. In 12-bit mode, the ADC throughput is reduced by a factor of 4.
	Value	Name	Description	
	0	12_BIT_DISABLED	Disable 12-bit mode.	
	1	12_BIT_ENABLED	Enable 12-bit mode.	
6	ADAE	0	RW	<b>Accumulate Enable.</b> Enables multiple conversions to be accumulated when burst mode is disabled.
	Value	Name	Description	
	0	ACC_DISABLED	ADC0H:ADC0L contain the result of the latest conversion when Burst Mode is disabled.	
	1	ACC_ENABLED	ADC0H:ADC0L contain the accumulated conversion results when Burst Mode is disabled. Firmware must write 0x0000 to ADC0H:ADC0L to clear the accumulated result.	
5:3	ADSJST	0x0	RW	<b>Accumulator Shift and Justify.</b> Specifies the format of data read from ADC0H:ADC0L. All remaining bit combinations are reserved.
	Value	Name	Description	
	0x0	RIGHT_NO_SHIFT	Right justified. No shifting applied.	
	0x1	RIGHT_SHIFT_1	Right justified. Shifted right by 1 bit.	
	0x2	RIGHT_SHIFT_2	Right justified. Shifted right by 2 bits.	
	0x3	RIGHT_SHIFT_3	Right justified. Shifted right by 3 bits.	
	0x4	LEFT_NO_SHIFT	Left justified. No shifting applied.	
2:0	ADRPT	0x0	RW	<b>Repeat Count.</b> Selects the number of conversions to perform and accumulate in Burst Mode. This bit field must be set to 000 if Burst Mode is disabled.
	Value	Name	Description	
	0x0	ACC_1	Perform and Accumulate 1 conversion (not used in 12-bit mode).	
	0x1	ACC_4	Perform and Accumulate 4 conversions (1 conversion in 12-bit mode).	
	0x2	ACC_8	Perform and Accumulate 8 conversions (2 conversions in 12-bit mode).	
	0x3	ACC_16	Perform and Accumulate 16 conversions (4 conversions in 12-bit mode).	
	0x4	ACC_32	Perform and Accumulate 32 conversions (8 conversions in 12-bit mode).	

Bit	Name	Reset	Access	Description
	0x5	ACC_64		Perform and Accumulate 64 conversions (16 conversions in 12-bit mode).

The required tracking time for the first conversion should be defined with the ADPWR field.</p>									

### 12.4.7 ADC0H: ADC0 Data Word High Byte

Bit	7	6	5	4	3	2	1	0
Name	ADC0H							
Access	RW							
Reset	0x00							
SFR Address: 0xBE								

Bit	Name	Reset	Access	Description
7:0	ADC0H	0x00	RW	<p><b>Data Word High Byte.</b></p> <p>When read, this register returns the most significant byte of the 16-bit ADC0 accumulator, formatted according to the settings in ADSJST. The register may also be written, to set the upper byte of the 16-bit ADC0 accumulator.</p> <p>If Accumulator shifting is enabled, the most significant bits of the value read will be zeros.</p>

### 12.4.8 ADC0L: ADC0 Data Word Low Byte

Bit	7	6	5	4	3	2	1	0
Name	ADC0L							
Access	RW							
Reset	0x00							
SFR Address: 0xBD								

Bit	Name	Reset	Access	Description
7:0	ADC0L	0x00	RW	<b>Data Word Low Byte.</b> When read, this register returns the least significant byte of the 16-bit ADC0 accumulator, formatted according to the settings in ADSJST. The register may also be written, to set the lower byte of the 16-bit ADC0 accumulator. If Accumulator shifting is enabled, the most significant bits of the value read will be zeros.

### 12.4.9 ADC0GTH: ADC0 Greater-Than High Byte

Bit	7	6	5	4	3	2	1	0
Name	ADC0GTH							
Access	RW							
Reset	0xFF							
SFR Address: 0xC4								

Bit	Name	Reset	Access	Description
7:0	ADC0GTH	0xFF	RW	<b>Greater-Than High Byte.</b> Most significant byte of the 16-bit greater-than window compare register.

### 12.4.10 ADC0GTL: ADC0 Greater-Than Low Byte

Bit	7	6	5	4	3	2	1	0
Name	ADC0GTL							
Access	RW							
Reset	0xFF							
SFR Address: 0xC3								

Bit	Name	Reset	Access	Description
7:0	ADC0GTL	0xFF	RW	<b>Greater-Than Low Byte.</b> Least significant byte of the 16-bit greater-than window compare register. In 8-bit mode, this register should be set to 0x00.

#### 12.4.11 ADC0LTH: ADC0 Less-Than High Byte

Bit	7	6	5	4	3	2	1	0
Name	ADC0LTH							
Access	RW							
Reset	0x00							
SFR Address: 0xC6								

Bit	Name	Reset	Access	Description
7:0	ADC0LTH	0x00	RW	<b>Less-Than High Byte.</b> Most significant byte of the 16-bit less-than window compare register.

#### 12.4.12 ADC0LTL: ADC0 Less-Than Low Byte

Bit	7	6	5	4	3	2	1	0
Name	ADC0LTL							
Access	RW							
Reset	0x00							
SFR Address: 0xC5								

Bit	Name	Reset	Access	Description
7:0	ADC0LTL	0x00	RW	<b>Less-Than Low Byte.</b> Least significant byte of the 16-bit less-than window compare register.
In 8-bit mode, this register should be set to 0x00.				

#### 12.4.13 ADC0MX: ADC0 Multiplexer Selection

Bit	7	6	5	4	3	2	1	0
Name	Reserved			ADC0MX				
Access	R			RW				
Reset	0x0			0x1F				
SFR Address: 0xBB								

Bit	Name	Reset	Access	Description
7:5	<i>Reserved</i>	<i>Must write reset value.</i>		
4:0	ADC0MX	0x1F	RW	<b>AMUX0 Positive Input Selection.</b> Selects the positive input channel for ADC0. For reserved bit combinations, no input is selected.

### 12.4.14 REF0CN: Voltage Reference Control

Bit	7	6	5	4	3	2	1	0
Name	IREFLVL	Reserved	GNDSL	REFSL		TEMPE	Reserved

Value	Name	Description																	
0	GND_PIN	The ADC0 ground reference is the GND pin.																	
1	AGND_PIN	The ADC0 ground reference is the P0.1/AGND pin.																	
4:3	REFSL	0x3	RW	<b>Voltage Reference Select.</b> Selects the ADC0 voltage reference.  <table border="1"> <thead> <tr> <th>Value</th> <th>Name</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>VREF_PIN</td> <td>The ADC0 voltage reference is the P0.0/VREF pin.</td> </tr> <tr> <td>0x1</td> <td>VDD_PIN</td> <td>The ADC0 voltage reference is the VDD pin.</td> </tr> <tr> <td>0x2</td> <td>INTERNAL_LDO</td> <td>The ADC0 voltage reference is the internal 1.8 V digital supply voltage.</td> </tr> <tr> <td>0x3</td> <td>INTERNAL_VREF</td> <td>The ADC0 voltage reference is the internal voltage reference.</td> </tr> </tbody> </table>	Value	Name	Description	0x0	VREF_PIN	The ADC0 voltage reference is the P0.0/VREF pin.	0x1	VDD_PIN	The ADC0 voltage reference is the VDD pin.	0x2	INTERNAL_LDO	The ADC0 voltage reference is the internal 1.8 V digital supply voltage.	0x3	INTERNAL_VREF	The ADC0 voltage reference is the internal voltage reference.
Value	Name	Description																	
0x0	VREF_PIN	The ADC0 voltage reference is the P0.0/VREF pin.																	
0x1	VDD_PIN	The ADC0 voltage reference is the VDD pin.																	
0x2	INTERNAL_LDO	The ADC0 voltage reference is the internal 1.8 V digital supply voltage.																	
0x3	INTERNAL_VREF	The ADC0 voltage reference is the internal voltage reference.																	
2	TEMPE	0	RW	<b>Temperature Sensor Enable.</b> Enables/Disables the internal temperature sensor.  <table border="1"> <thead> <tr> <th>Value</th> <th>Name</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>TEMP_DISABLED</td> <td>Disable the Temperature Sensor.</td> </tr> <tr> <td>1</td> <td>TEMP_ENABLED</td> <td>Enable the Temperature Sensor.</td> </tr> </tbody> </table>	Value	Name	Description	0	TEMP_DISABLED	Disable the Temperature Sensor.	1	TEMP_ENABLED	Enable the Temperature Sensor.						
Value	Name	Description																	
0	TEMP_DISABLED	Disable the Temperature Sensor.																	
1	TEMP_ENABLED	Enable the Temperature Sensor.																	
1:0	<i>Reserved</i>	<i>Must write reset value.</i>																	

## 13. Comparators (CMP0 and CMP1)

### 13.1 Introduction

Analog comparators are used to compare the voltage of two analog inputs, with a digital output indicating which input voltage is higher. External input connections to device I/O pins and internal connections are available through separate multiplexers on the positive and negative inputs. Hysteresis, response time, and current consumption may be programmed to suit the specific needs of the application.

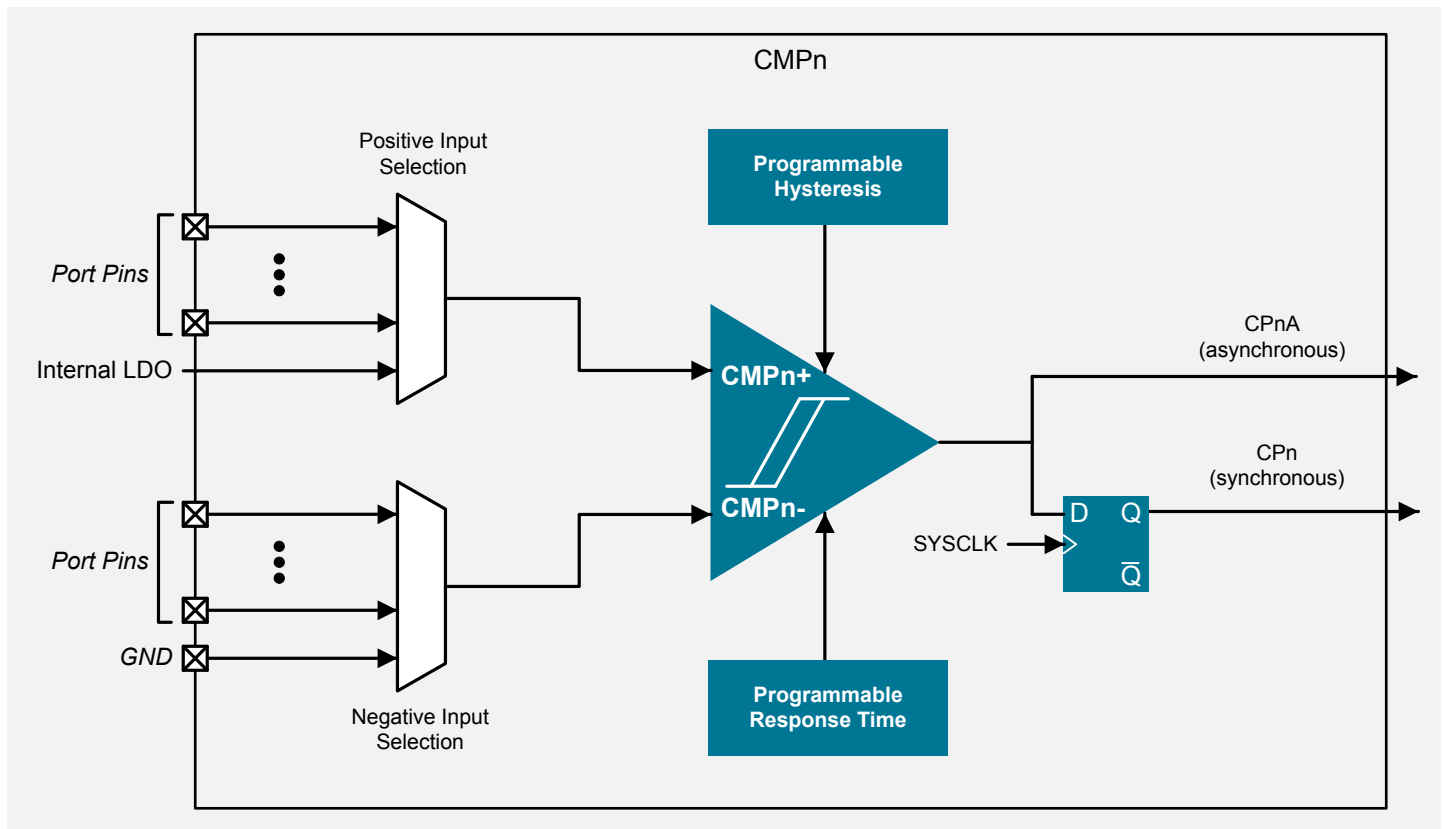

Figure 13.1. Comparator Block Diagram

### 13.2 Features

The comparator module includes the following features:

- Up to 8 external positive inputs.
- Up to 8 external negative inputs.
- Additional input options:
  - Internal connection to LDO output.
  - Direct connection to GND.
- Synchronous and asynchronous outputs can be routed to pins via crossbar.
- Programmable hysteresis between 0 and  $\pm 20$  mV
- Programmable response time.
- Interrupts generated on rising, falling, or both edges.

### 13.3 Functional Description

#### 13.3.1 Response Time and Supply Current

Response time is the amount of time delay between a change at the comparator inputs and the comparator's reaction at the output. The comparator response time may be configured in software via the CPMD field in the CMPnMD register. Selecting a longer response time reduces the comparator supply current, while shorter response times require more supply current.

### 13.3.2 Hysteresis

The comparator hysteresis is software-programmable via its Comparator Control register CMPnCN. The user can program both the amount of hysteresis voltage (referred to the input voltage) and the positive and negative-going symmetry of this hysteresis around the threshold voltage.

The comparator hysteresis is programmable using the CPHYN and CPHYP fields in the Comparator Control Register CMPnCN. The amount of negative hysteresis voltage is determined by the settings of the CPHYN bits. Settings of 20, 10, or 5 mV (nominal) of negative hysteresis can be programmed, or negative hysteresis can be disabled. In a similar way, the amount of positive hysteresis is determined by the setting the CPHYP bits.

Figure 13.2. Comparator Hysteresis Plot

### 13.3.3 Input Selection

Comparator inputs may be routed to port I/O pins or internal signals. When connected externally, the comparator inputs can be driven from  $-0.25\text{ V}$  to  $(\text{VDD}) + 0.25\text{ V}$  without damage or upset. The CMPnMX register selects the inputs for the associated comparator. The CMXP field selects the comparator's positive input (CPnP.x) and the CMXN field selects the comparator's negative input (CPnN.x).

**Note:** Any port pins selected as comparator inputs should be configured as analog inputs in their associated port configuration register, and configured to be skipped by the crossbar.

### 13.3.3.1 Multiplexer Channel Selection

**Table 13.1. CMP0 Positive Input Multiplexer Channels**

CMXP Setting in Register CMP0MX	Signal Name	Enumeration Name	QSOP24 Pin Name	QFN20 Pin Name	SOIC16 Pin Name

1001-1111	CMP1P.9 - CMP1P.15	NONE	No connection / Reserved		

### 13.3.4 Output Routing

The comparator's synchronous and asynchronous outputs can optionally be routed to port I/O pins through the port I/O crossbar. The output of either comparator may be configured to generate a system interrupt on rising, falling, or both edges. CMP0 may also be used as a reset source or as a trigger to kill a PCA output channel.

The output state of the comparator can be obtained at any time by reading the CPOUT bit. The comparator is enabled by setting the CPEN bit to logic 1, and is disabled by clearing this bit to logic 0. When disabled, the comparator output (if assigned to a port I/O pin via the crossbar) defaults to the logic low state, and the power supply to the comparator is turned off.

Comparator interrupts can be generated on both rising-edge and falling-edge output transitions. The CPFIF flag is set to logic 1 upon a comparator falling-edge occurrence, and the CPRIF flag is set to logic 1 upon the comparator rising-edge occurrence. Once set, these bits remain set until cleared by software. The comparator rising-edge interrupt mask is enabled by setting CPRIE to a logic 1. The comparator falling-edge interrupt mask is enabled by setting CPFIE to a logic 1.

False rising edges and falling edges may be detected when the comparator is first powered on or if changes are made to the hysteresis or response time control bits. Therefore, it is recommended that the rising-edge and falling-edge flags be explicitly cleared to logic 0 a short time after the comparator is enabled or its mode bits have been changed, before enabling comparator interrupts.

## 13.4 CMP0 Control Registers

### 13.4.1 CMP0CN0: Comparator 0 Control 0

Bit	7	6	5	4	3	2	1	0
Name	CPEN	CPOUT	CPRIF	CPFIF	CPHYP		CPHYN

3:0	CMXP	0xF	RW	<b>Comparator Positive Input MUX Selection.</b> This field selects the positive input for the comparator.

## 14. Cyclic Redundancy Check (CRC0)

### 14.1 Introduction

The cyclic redundancy check (CRC) module performs a CRC using a 16-bit polynomial. CRC0 accepts a stream of 8-bit data and posts the 16-bit result to an internal register. In addition to using the CRC block for data manipulation, hardware can automatically CRC the flash contents of the device.

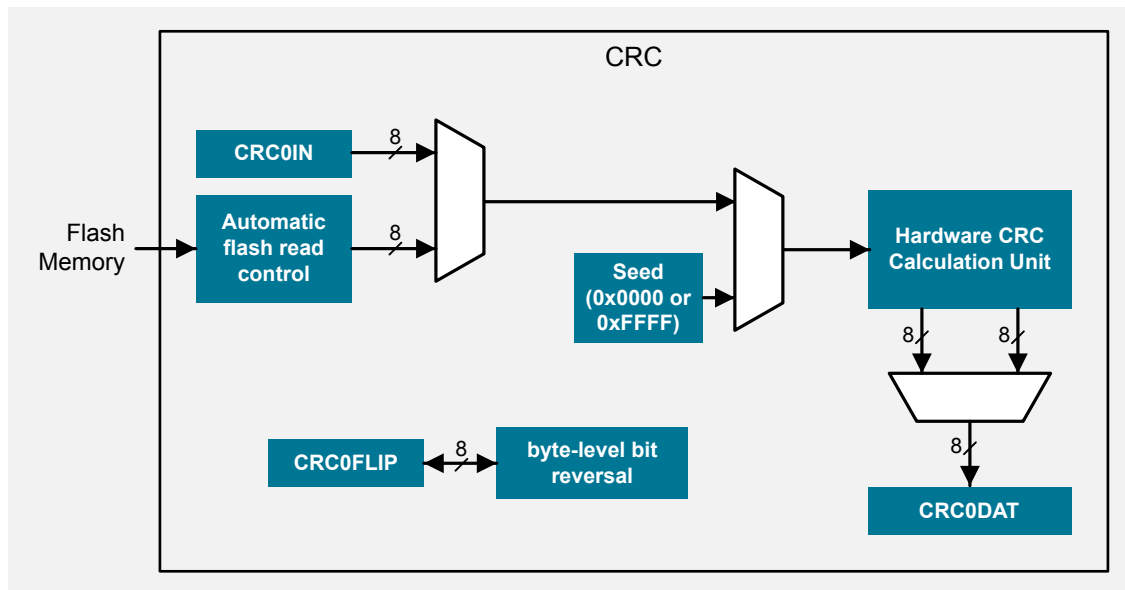

Figure 14.1. CRC Functional Block Diagram

### 14.2 Features

The CRC module is designed to provide hardware calculations for flash memory verification and communications protocols. The CRC module supports the standard CCITT-16 16-bit polynomial (0x1021), and includes the following features:

- Support for CCITT-16 polynomial
- Byte-level bit reversal
- Automatic CRC of flash contents on one or more 256-byte blocks
- Initial seed selection of 0x0000 or 0xFFFF

## 14.3 Functional Description

### 14.3.1 16-bit CRC Algorithm

The CRC unit generates a 16-bit CRC result equivalent to the following algorithm:

1. XOR the input with the most-significant bits of the current CRC result. If this is the first iteration of the CRC unit, the current CRC result will be the set initial value (0x0000 or 0xFFFF).
2. If the MSB of the CRC result is set, shift the CRC result and XOR the result with the polynomial.
3. If the MSB of the CRC result is not set, shift the CRC result.
4. Repeat steps 2 and 3 for all 8 bits.

The algorithm is also described in the following example.

```

unsigned short UpdateCRC (unsigned short CRC_acc, unsigned char CRC_input)
{
    unsigned char i; // loop counter
    #define POLY 0x1021

    // Create the CRC "dividend" for polynomial arithmetic (binary arithmetic
    // with no carries)
    CRC_acc = CRC_acc ^ (CRC_input << 8);

    // "Divide" the poly into the dividend using CRC XOR subtraction
    // CRC_acc holds the "remainder" of each divide
    //
    // Only complete this division for 8 bits since input is 1 byte
    for (i = 0; i < 8; i++)
    {
        // Check if the MSB is set (if MSB is 1, then the POLY can "divide"
        // into the "dividend")
        if ((CRC_acc & 0x8000) == 0x8000)
        {
            // if so, shift the CRC value, and XOR "subtract" the poly
            CRC_acc = CRC_acc << 1;
            CRC_acc ^= POLY;
        }
        else
        {
            // if not, just shift the CRC value
            CRC_acc = CRC_acc << 1;
        }
    }

    // Return the final remainder (CRC value)
    return CRC_acc;
}
    
```

The following table lists several input values and the associated outputs using the 16-bit CRC algorithm:

**Table 14.1. Example 16-bit CRC Outputs**

Input	Output
0x63	0xBD35
0x8C	0xB1F4
0x7D	0x4ECA
0xAA, 0xBB, 0xCC	0x6CF6
0x00, 0x00, 0xAA, 0xBB, 0xCC	0xB166

### 14.3.2 Using the CRC on a Data Stream

The CRC module may be used to perform CRC calculations on any data set available to the firmware. To perform a CRC on an arbitrary data stream:

1. Select the initial result value using CRCVAL.
2. Set the result to its initial value (write 1 to CRCINIT).
3. Write the data to CRC0IN one byte at a time. The CRC result registers are automatically updated after each byte is written.
4. Write the CRCPNT bit to 0 to target the low byte of the result.
5. Read CRC0DAT multiple times to access each byte of the CRC result. CRCPNT will automatically point to the next value after each read.

### 14.3.3 Using the CRC to Check Code Memory

The CRC module may be configured to automatically perform a CRC on one or more blocks of code memory. To perform a CRC on code contents:

1. Select the initial result value using CRCVAL.
2. Set the result to its initial value (write 1 to CRCINIT).
3. Write the high byte of the starting address to the CRCST bit field.
4. Set the AUTOEN bit to 1.
5. Write the number of byte blocks to perform in the CRC calculation to CRCCNT.
6. Write any value to CRC0CN0 (or OR its contents with 0x00) to initiate the CRC calculation. The CPU will not execute code any additional code until the CRC operation completes.

**Note:** Upon initiation of an automatic CRC calculation, the three cycles following a write to CRC0CN0 that initiate a CRC operation must only contain instructions which execute in the same number of cycles as the number of bytes in the instruction. An example of such an instruction is a 3-byte MOV that targets the CRC0FLIP register. When programming in C, the dummy value written to CRC0FLIP should be a non-zero value to prevent the compiler from generating a 2-byte MOV instruction.

7. Clear the AUTOEN.
8. Write the CRCPNT bit to 0 to target the low byte of the result.
9. Read CRC0DAT multiple times to access each byte of the CRC result. CRCPNT will automatically point to the next value after each read.

### 14.3.4 Bit Reversal

CRC0 includes hardware to reverse the bit order of each bit in a byte. Writing a byte to CRC0FLIP initiates the bit reversal operation, and the result may be read back from CRC0FLIP on the next instruction. For example, if 0xC0 is written to CRC0FLIP, the data read back is 0x03. Bit reversal can be used to change the order of information passing through the CRC engine and is also used in algorithms such as FFT.

## 14.4 CRC0 Control Registers

### 14.4.1 CRC0CN0: CRC0 Control 0

Bit	7	6	5	4	3	2	1	0
Name	Reserved				CRCINIT	CRCVAL	Reserved	CRCPNT
Access	R				RW	RW	R	RW
Reset	0x1				0	0	0	0
SFR Address: 0xCE								

Bit	Name	Reset	Access	Description									
7:4	<i>Reserved</i>	<i>Must write reset value.</i>											
3	CRCINIT	0	RW	<b>CRC Initialization Enable.</b> Writing a 1 to this bit initializes the entire CRC result based on CRCVAL.									
2	CRCVAL	0	RW	<b>CRC Initialization Value.</b> This bit selects the set value of the CRC result.  <table border="1"> <thead> <tr> <th>Value</th> <th>Name</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>SET_ZEROES</td> <td>CRC result is set to 0x0000 on write of 1 to CRCINIT.</td> </tr> <tr> <td>1</td> <td>SET_ONES</td> <td>CRC result is set to 0xFFFF on write of 1 to CRCINIT.</td> </tr> </tbody> </table>	Value	Name	Description	0	SET_ZEROES	CRC result is set to 0x0000 on write of 1 to CRCINIT.	1	SET_ONES	CRC result is set to 0xFFFF on write of 1 to CRCINIT.
Value	Name	Description											
0	SET_ZEROES	CRC result is set to 0x0000 on write of 1 to CRCINIT.											
1	SET_ONES	CRC result is set to 0xFFFF on write of 1 to CRCINIT.											
1	<i>Reserved</i>	<i>Must write reset value.</i>											
0	CRCPNT	0	RW	<b>CRC Result Pointer.</b> Specifies the byte of the CRC result to be read/written on the next access to CRC0DAT. This bit will automatically toggle upon each read or write.  <table border="1"> <thead> <tr> <th>Value</th> <th>Name</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>ACCESS_LOWER</td> <td>CRC0DAT accesses bits 7-0 of the 16-bit CRC result.</td> </tr> <tr> <td>1</td> <td>ACCESS_UPPER</td> <td>CRC0DAT accesses bits 15-8 of the 16-bit CRC result.</td> </tr> </tbody> </table>	Value	Name	Description	0	ACCESS_LOWER	CRC0DAT accesses bits 7-0 of the 16-bit CRC result.	1	ACCESS_UPPER	CRC0DAT accesses bits 15-8 of the 16-bit CRC result.
Value	Name	Description											
0	ACCESS_LOWER	CRC0DAT accesses bits 7-0 of the 16-bit CRC result.											
1	ACCESS_UPPER	CRC0DAT accesses bits 15-8 of the 16-bit CRC result.											

Upon initiation of an automatic CRC calculation, the three cycles following a write to CRC0CN0 that initiate a CRC operation must only contain instructions which execute in the same number of cycles as the number of bytes in the instruction. An example of such an instruction is a 3-byte MOV that targets the CRC0FLIP register. When programming in C, the dummy value written to CRC0FLIP should be a non-zero value to prevent the compiler from generating a 2-byte MOV instruction.

### 14.4.2 CRC0IN: CRC0 Data Input

Bit	7	6	5	4	3	2	1	0
Name	CRC0IN							
Access	RW							
Reset	0x00							
SFR Address: 0xDD								

Bit	Name	Reset	Access	Description
7:0	CRC0IN	0x00	RW	<b>CRC Data Input.</b> Each write to CRC0IN results in the written data being computed into the existing CRC result according to the CRC algorithm.

### 14.4.3 CRC0DAT: CRC0 Data Output

Bit	7	6	5	4	3	2	1	0
Name	CRC0DAT							
Access	RW							
Reset	0x00							
SFR Address: 0xDE								

Bit	Name	Reset	Access	Description
7:0	CRC0DAT	0x00	RW	<b>CRC Data Output.</b> Each read or write performed on CRC0DAT targets the CRC result bits pointed to by the CRC0 Result Pointer (CRCPNT bits in CRC0CN0).
CRC0DAT may not be valid for one cycle after setting the CRCINIT bit in the CRC0CN0 register to 1. Any time CRCINIT is written to 1 by firmware, at least one instruction should be performed before reading CRC0DAT.				

### 14.4.4 CRC0AUTO: CRC0 Automatic Control

Bit	7	6	5	4	3	2	1	0
Name	AUTOEN	Reserved	CRCST					
Access	RW	R	RW					
Reset	0	0	0x00					
SFR Address: 0xD2								

Bit	Name	Reset	Access	Description
7	AUTOEN	0	RW	<b>Automatic CRC Calculation Enable.</b> When AUTOEN is set to 1, any write to CRC0CN0 will initiate an automatic CRC starting at flash sector CRCST and continuing for CRCCNT sectors.
6	<i>Reserved</i>	<i>Must write reset value.</i>		
5:0	CRCST	0x00	RW	<b>Automatic CRC Calculation Starting Block.</b> These bits specify the flash block to start the automatic CRC calculation. The starting address of the first flash block included in the automatic CRC calculation is CRCST x block_size, where block_size is 256 bytes.

#### 14.4.5 CRC0CNT: CRC0 Automatic Flash Sector Count

Bit	7	6	5	4	3	2	1	0
Name	CRCDN	Reserved			CRCCNT			
Access	R	R			RW			
Reset	1	0x0			0x00			
SFR Address: 0xD3								

Bit	Name	Reset	Access	Description
7	CRCDN	1	R	<b>Automatic CRC Calculation Complete.</b> Set to 0 when a CRC calculation is in progress. Code execution is stopped during a CRC calculation; therefore, reads from firmware will always return 1.
6:5	<i>Reserved</i>	<i>Must write reset value.</i>		
4:0	CRCCNT	0x00	RW	<b>Automatic CRC Calculation Block Count.</b> These bits specify the number of flash blocks to include in an automatic CRC calculation. The last address of the last flash block included in the automatic CRC calculation is $(CRCST+CRCCNT) \times \text{Block Size} - 1$ . The block size is 256 bytes.

#### 14.4.6 CRC0FLIP: CRC0 Bit Flip

Bit	7	6	5	4	3	2	1	0
Name	CRC0FLIP							
Access	RW							
Reset	0x00							
SFR Address: 0xCF								

Bit	Name	Reset	Access	Description
7:0	CRC0FLIP	0x00	RW	<b>CRC0 Bit Flip.</b> Any byte written to CRC0FLIP is read back in a bit-reversed order, i.e., the written LSB becomes the MSB. For example: If 0xC0 is written to CRC0FLIP, the data read back will be 0x03. If 0x05 is written to CRC0FLIP, the data read back will be 0xA0.

## 15. Programmable Counter Array (PCA0)

### 15.1 Introduction

The programmable counter array (PCA) provides multiple channels of enhanced timer and PWM functionality while requiring less CPU intervention than standard counter/timers. The PCA consists of a dedicated 16-bit counter/timer and one 16-bit capture/compare module for each channel. The counter/timer is driven by a programmable timebase that has flexible external and internal clocking options. Each capture/compare module may be configured to operate independently in one of five modes: Edge-Triggered Capture, Software Timer, High-Speed Output, Frequency Output, or Pulse-Width Modulated (PWM) Output. Each capture/compare module has its own associated I/O line (CEXn) which is routed through the crossbar to port I/O when enabled.

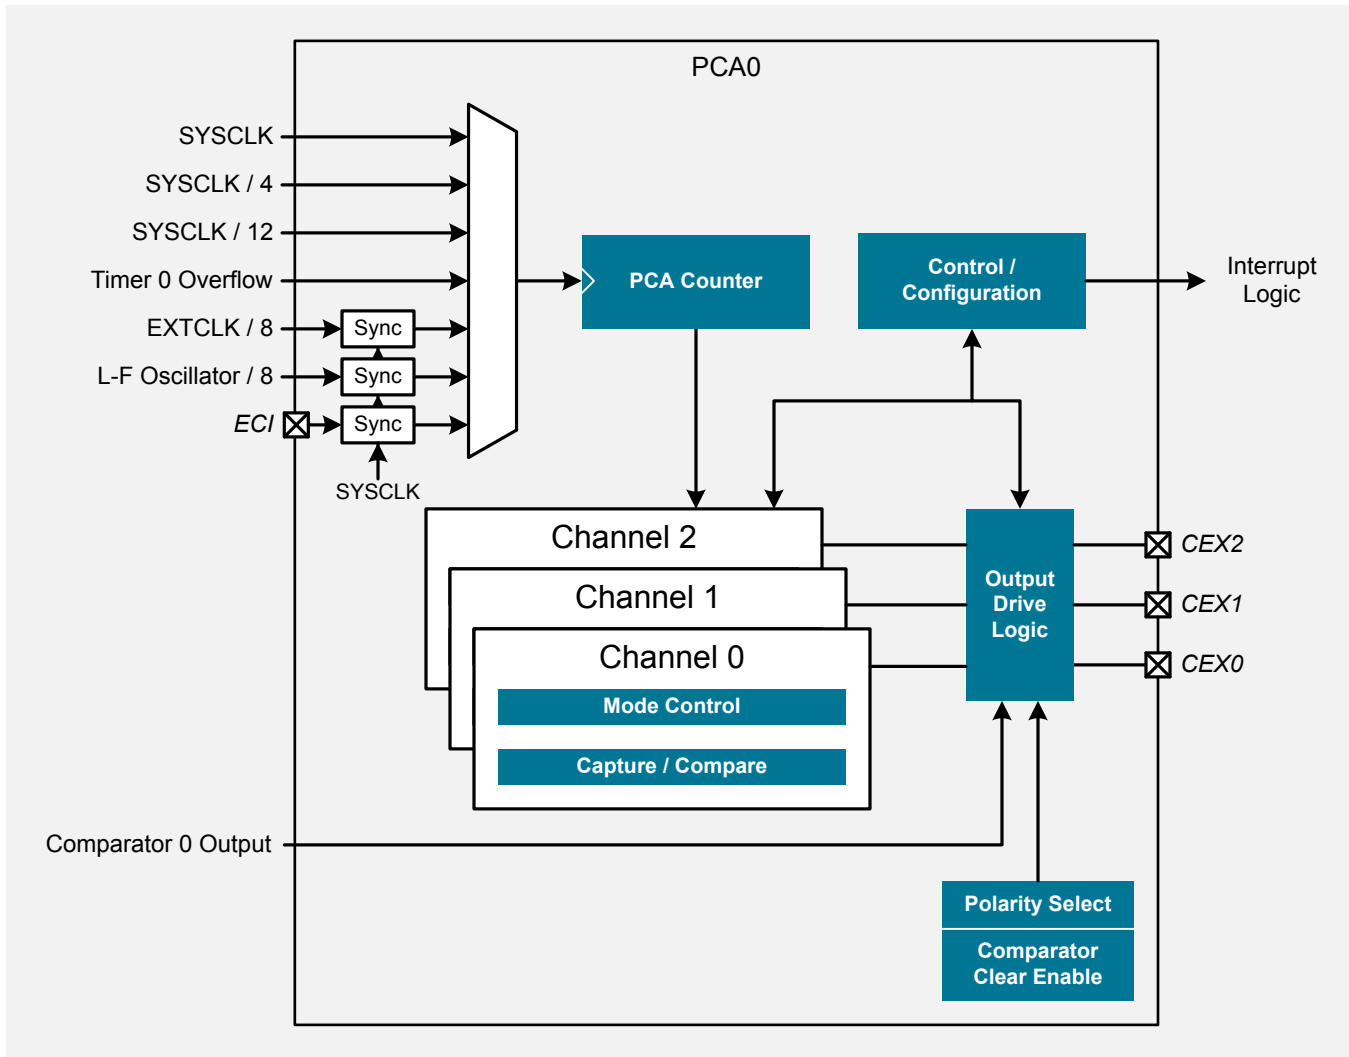

Figure 15.1. PCA Block Diagram

## 15.2 Features

- 16-bit time base
- Programmable clock divisor and clock source selection
- Up to three independently-configurable channels
- 8, 9, 10, 11 and 16-bit PWM modes (center or edge-aligned operation)
- Output polarity control
- Frequency output mode
- Capture on rising, falling or any edge
- Compare function for arbitrary waveform generation
- Software timer (internal compare) mode
- Can accept hardware “kill” signal from comparator 0

## 15.3 Functional Description

### 15.3.1 Counter / Timer

The 16-bit PCA counter/timer consists of two 8-bit SFRs: PCA0L and PCA0H. PCA0H is the high byte of the 16-bit counter/timer and PCA0L is the low byte. Reading PCA0L automatically latches the value of PCA0H into a “snapshot” register; the following PCA0H read accesses this “snapshot” register.

**Note:** Reading the PCA0L Register first guarantees an accurate reading of the entire 16-bit PCA0 counter.

Reading PCA0H or PCA0L does not disturb the counter operation. The CPS2–CPS0 bits in the PCA0MD register select the timebase for the counter/timer.

When the counter/timer overflows from 0xFFFF to 0x0000, the Counter Overflow Flag (CF) in PCA0MD is set to logic 1 and an interrupt request is generated if CF interrupts are enabled. Setting the ECF bit in PCA0MD to logic 1 enables the CF flag to generate an interrupt request. The CF bit is not automatically cleared by hardware when the CPU vectors to the interrupt service routine and must be cleared by software. Clearing the CIDL bit in the PCA0MD register allows the PCA to continue normal operation while the CPU is in Idle mode.

**Table 15.1. PCA Timebase Input Options**

CPS2:0	Timebase
000	System clock divided by 12
001	System clock divided by 4
010	Timer 0 overflow
011	High-to-low transitions on ECI (max rate = system clock divided by 4) <sup>1</sup>
100	System clock
101	External oscillator source divided by 8 <sup>1</sup>
110	Low frequency oscillator divided by 8 <sup>1</sup>
111	Reserved
<b>Note:</b>	
1. Synchronized with the system clock.	

### 15.3.2 Interrupt Sources

The PCA0 module shares one interrupt vector among all of its modules. There are several event flags that can be used to generate a PCA0 interrupt. They are as follows: the main PCA counter overflow flag (CF), which is set upon a 16-bit overflow of the PCA0 counter; an intermediate overflow flag (COVF), which can be set on an overflow from the 8th–11th bit of the PCA0 counter; and the individual flags for each PCA channel (CCFn), which are set according to the operation mode of that module. These event flags are always set when the trigger condition occurs. Each of these flags can be individually selected to generate a PCA0 interrupt using the corresponding interrupt enable flag (ECF for CF, ECOV for COVF, and ECCFn for each CCFn). PCA0 interrupts must be globally enabled before any individual interrupt sources are recognized by the processor. PCA0 interrupts are globally enabled by setting the EA bit and the EPCA0 bit to logic 1.

### 15.3.3 Capture/Compare Modules

Each module can be configured to operate independently in one of six operation modes: edge-triggered capture, software timer, high-speed output, frequency output, 8 to 11-bit pulse width modulator, or 16-bit pulse width modulator. [Table 15.2 PCA0CPM and PCA0PWM Bit Settings for PCA Capture/Compare Modules](#) on page 135 summarizes the bit settings in the PCA0CPMn and PCA0PWM registers used to select the PCA capture/compare module's operating mode. All modules set to use 8-, 9-, 10-, or 11-bit PWM mode must use the same cycle length (8–11 bits). Setting the ECCFn bit in a PCA0CPMn register enables the module's CCFn interrupt.

**Table 15.2. PCA0CPM and PCA0PWM Bit Settings for PCA Capture/Compare Modules**

Operational Mode	PCA0CPMn								PCA0PWM				
	PWM16	ECOM	CAPP	CAPN	MAT	TOG	PWM	ECCF	ARSEL	ECOV	COVF	Reserved	CLSEL
Capture triggered by positive edge on CEXn	X	X	1	0	0	0	0	A	0	X	B	X	X
Capture triggered by negative edge on CEXn	X	X	0	1	0	0	0	A	0	X	B	X	X
Capture triggered by any transition on CEXn	X	X	1	1	0	0	0	A	0	X	B	X	X
Software Timer	X	C	0	0	1	0	0	A	0	X	B	X	X
High Speed Output	X	C	0	0	1	1	0	A	0	X	B	X	X
Frequency Output	X	C	0	0	0	1	1	A	0	X	B	X	X
8-Bit Pulse Width Modulator <sup>7</sup>	0	C	0	0	E	0	1	A	0	X	B	X	0
9-Bit Pulse Width Modulator <sup>7</sup>	0	C	0	0	E	0	1	A	D	X	B	X	1
10-Bit Pulse Width Modulator <sup>7</sup>	0	C	0	0	E	0	1	A	D	X	B	X	2
11-Bit Pulse Width Modulator <sup>7</sup>	0	C	0	0	E	0	1	A	D	X	B	X	3
16-Bit Pulse Width Modulator	1	C	0	0	E	0	1	A	0	X	B	X	X

**Notes:**

1. X = Don't Care (no functional difference for individual module if 1 or 0).
2. A = Enable interrupts for this module (PCA interrupt triggered on CCFn set to 1).
3. B = Enable 8th–11th bit overflow interrupt (Depends on setting of CLSEL).
4. C = When set to 0, the digital comparator is off. For high speed and frequency output modes, the associated pin will not toggle. In any of the PWM modes, this generates a 0% duty cycle (output = 0).
5. D = Selects whether the Capture/Compare register (0) or the Auto-Reload register (1) for the associated channel is accessed via addresses PCA0CPHn and PCA0CPLn.
6. E = When set, a match event will cause the CCFn flag for the associated channel to be set.
7. All modules set to 8, 9, 10 or 11-bit PWM mode use the same cycle length setting.

#### 15.3.3.1 Output Polarity

The output polarity of each PCA channel is individually selectable using the PCA0POL register. By default, all output channels are configured to drive the PCA output signals (CEXn) with their internal polarity. When the CEXnPOL bit for a specific channel is set to 1, that channel's output signal will be inverted at the pin. All other properties of the channel are unaffected, and the inversion does not apply to PCA input signals. Changes in the PCA0POL register take effect immediately at the associated output pin.

### 15.3.4 Edge-Triggered Capture Mode

In this mode, a valid transition on the CEXn pin causes the PCA to capture the value of the PCA counter/timer and load it into the corresponding module's 16-bit capture/compare register (PCA0CPLn and PCA0CPHn). The CAPPn and CAPNn bits in the PCA0CPMn register are used to select the type of transition that triggers the capture: low-to-high transition (positive edge), high-to-low transition (negative edge), or either transition (positive or negative edge). When a capture occurs, the Capture/Compare Flag (CCFn) in PCA0CN0 is set to logic 1. An interrupt request is generated if the CCFn interrupt for that module is enabled. The CCFn bit is not automatically cleared by hardware when the CPU vectors to the interrupt service routine, and must be cleared by software. If both CAPPn and CAPNn bits are set to logic 1, then the state of the port pin associated with CEXn can be read directly to determine whether a rising-edge or falling-edge caused the capture.

Figure 15.2. PCA Capture Mode Diagram

**Note:** The CEXn input signal must remain high or low for at least 2 system clock cycles to be recognized by the hardware.

### 15.3.5 Software Timer (Compare) Mode

In Software Timer mode, the PCA counter/timer value is compared to the module's 16-bit capture/compare register (PCA0CPHn and PCA0CPLn). When a match occurs, the Capture/Compare Flag (CCFn) in PCA0CN0 is set to logic 1. An interrupt request is generated if the CCFn interrupt for that module is enabled. The CCFn bit is not automatically cleared by hardware when the CPU vectors to the interrupt service routine, and it must be cleared by software. Setting the ECOMn and MATn bits in the PCA0CPMn register enables Software Timer mode.

**Note:** When writing a 16-bit value to the PCA0 Capture/Compare registers, the low byte should always be written first. Writing to PCA0CPLn clears the ECOMn bit to 0; writing to PCA0CPHn sets ECOMn to 1.

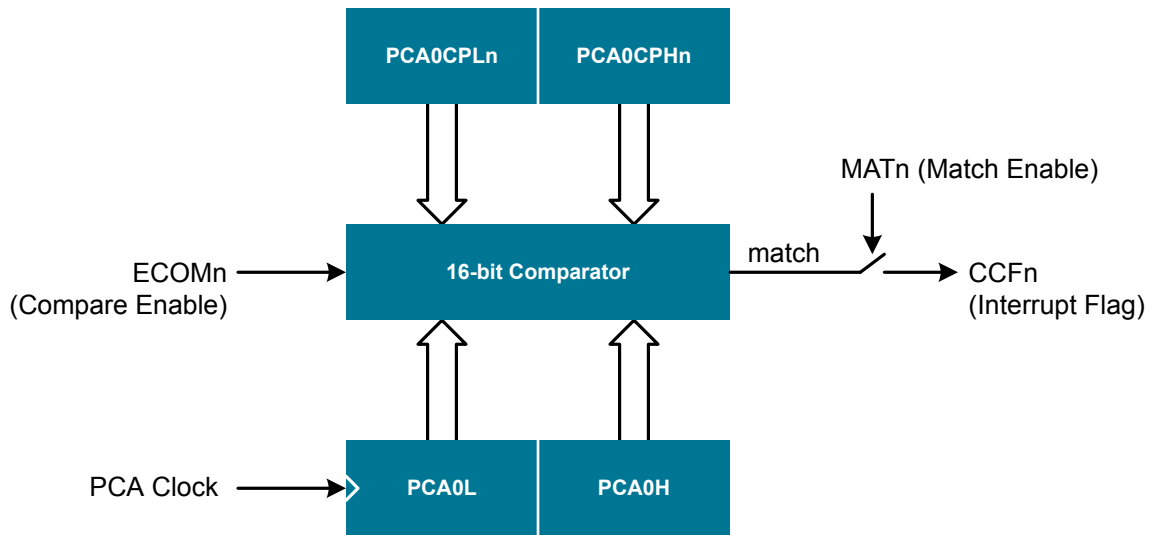

Figure 15.3. PCA Software Timer Mode Diagram

### 15.3.6 High-Speed Output Mode

In High-Speed Output mode, a module's associated CEXn pin is toggled each time a match occurs between the PCA Counter and the module's 16-bit capture/compare register (PCA0CPHn and PCA0CPLn). When a match occurs, the capture/compare flag (CCFn) in PCA0CN0 is set to logic 1. An interrupt request is generated if the CCFn interrupt for that module is enabled. The CCFn bit is not automatically cleared by hardware when the CPU vectors to the interrupt service routine. It must be cleared by software. Setting the TOGn, MATn, and ECOMn bits in the PCA0CPMn register enables the High-Speed Output mode. If ECOMn is cleared, the associated pin retains its state and not toggle on the next match event.

**Note:** When writing a 16-bit value to the PCA0 Capture/Compare registers, the low byte should always be written first. Writing to PCA0CPLn clears the ECOMn bit to 0; writing to PCA0CPHn sets ECOMn to 1.

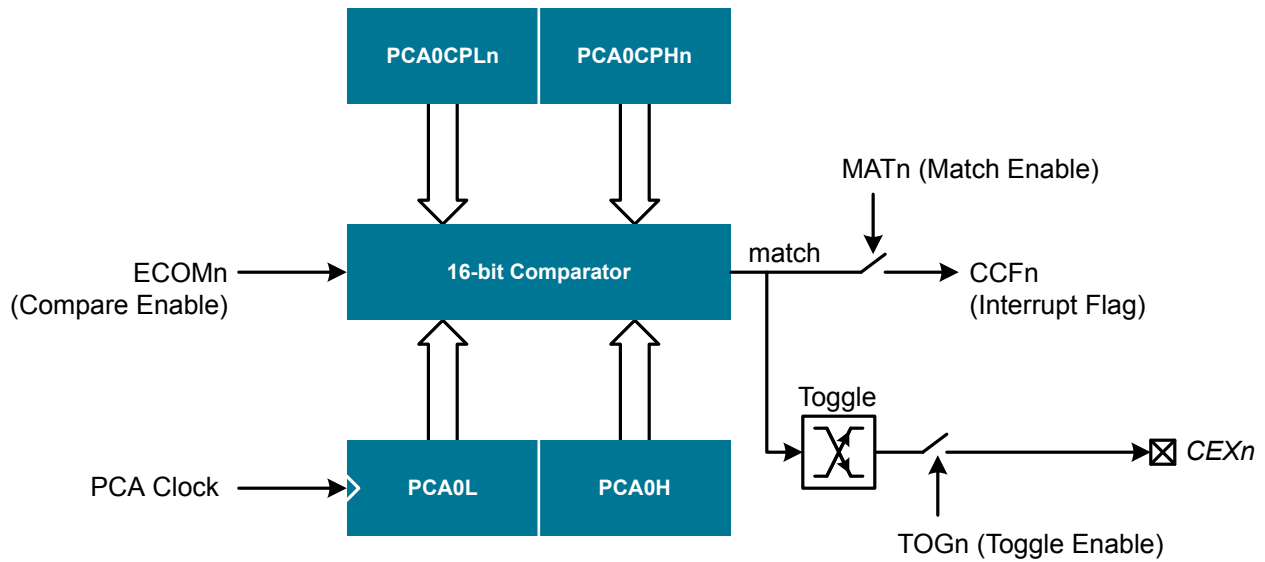

Figure 15.4. PCA High-Speed Output Mode Diagram

### 15.3.7 Frequency Output Mode

Frequency Output Mode produces a programmable-frequency square wave on the module's associated CEXn pin. The capture/compare module high byte holds the number of PCA clocks to count before the output is toggled. The frequency of the square wave is then defined as follows:

$$F_{CEXn} = \frac{F_{PCA}}{2 \times PCA0CPHn}$$

**Note:** A value of 0x00 in the PCA0CPHn register is equal to 256 for this equation.

Where  $F_{PCA}$  is the frequency of the clock selected by the CPS2–0 bits in the PCA mode register PCA0MD. The lower byte of the capture/compare module is compared to the PCA counter low byte; on a match, n is toggled and the offset held in the high byte is added to the matched value in PCA0CPLn. Frequency Output Mode is enabled by setting the ECOMn, TOGn, and PWMn bits in the PCA0CPMn register.

**Note:** The MATn bit should normally be set to 0 in this mode. If the MATn bit is set to 1, the CCFn flag for the channel will be set when the 16-bit PCA0 counter and the 16-bit capture/compare register for the channel are equal.

Figure 15.5. PCA Frequency Output Mode

### 15.3.8 PWM Waveform Generation

The PCA can generate edge- or center-aligned PWM waveforms with resolutions of 8, 9, 10, 11, or 16 bits. PWM resolution depends on the module setup, as specified within the individual module PCA0CPMn registers as well as the PCA0PWM register. Modules can be configured for 8-11 bit mode or for 16-bit mode individually using the PCA0CPMn registers. All modules configured for 8-11 bit mode have the same resolution, specified by the PCA0PWM register. When operating in one of the PWM modes, each module may be individually configured for center or edge-aligned PWM waveforms. Each channel has a single bit in the PCA0CENT register to select between the two options.

### Edge Aligned PWM

When configured for edge-aligned mode, a module generates an edge transition at two points for every  $2^N$  PCA clock cycles, where  $N$  is the selected PWM resolution in bits. In edge-aligned mode, these two edges are referred to as the “match” and “overflow” edges. The polarity at the output pin is selectable and can be inverted by setting the appropriate channel bit to 1 in the PCA0POL register. Prior to inversion, a match edge sets the channel to logic high, and an overflow edge clears the channel to logic low.

The match edge occurs when the the lowest  $N$  bits of the module’s PCA0CPn register match the corresponding bits of the main PCA0 counter register. For example, with 10-bit PWM, the match edge occurs any time bits 9-0 of the PCA0CPn register match bits 9-0 of the PCA0 counter value.

The overflow edge occurs when an overflow of the PCA0 counter happens at the desired resolution. For example, with 10-bit PWM, the overflow edge occurs when bits 0-9 of the PCA0 counter transition from all 1s to all 0s. All modules configured for edge-aligned mode at the same resolution align on the overflow edge of the waveforms.

An example of the PWM timing in edge-aligned mode for two channels is shown here. In this example, the CEX0POL and CEX1POL bits are cleared to 0.

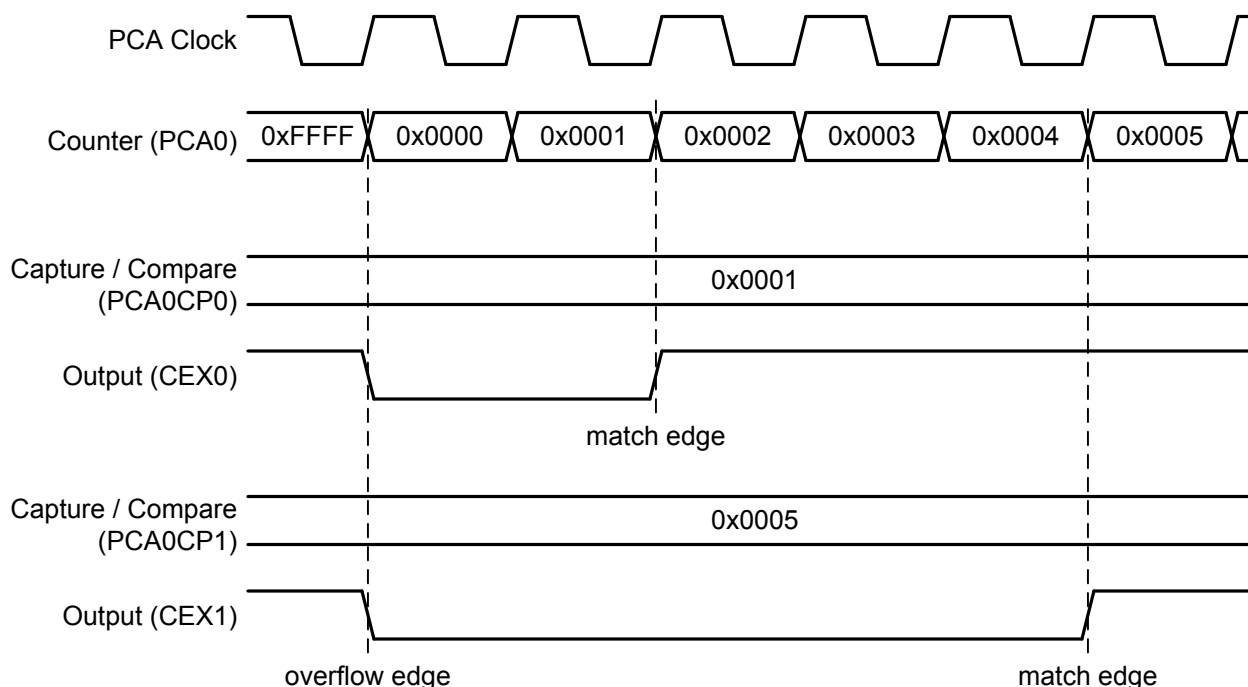

Figure 15.6. Edge-Aligned PWM Timing

For a given PCA resolution, the unused high bits in the PCA0 counter and the PCA0CPn compare registers are ignored, and only the used bits of the PCA0CPn register determine the duty cycle. [Figure 15.7 N-bit Edge-Aligned PWM Duty Cycle With CEXnPOL = 0 \(N = PWM resolution\) on page 140](#) describes the duty cycle when CEXnPOL in the PCA0POL register is cleared to 0. [Figure 15.8 N-bit Edge-Aligned PWM Duty Cycle With CEXnPOL = 1 \(N = PWM resolution\) on page 141](#) describes the duty cycle when CEXnPOL in the PCA0POL register is set to 1. A 0% duty cycle for the channel (with CEXnPOL = 0) is achieved by clearing the module’s ECOM bit to 0. This will disable the comparison, and prevent the match edge from occurring.

**Note:** Although the PCA0CPn compare register determines the duty cycle, it is not always appropriate for firmware to update this register directly. See the sections on 8 to 11-bit and 16-bit PWM mode for additional details on adjusting duty cycle in the various modes.

$$\text{Duty Cycle} = \frac{2^N - \text{PCA0CPn}}{2^N}$$

Figure 15.7. N-bit Edge-Aligned PWM Duty Cycle With CEXnPOL = 0 (N = PWM resolution)

$$\text{Duty Cycle} = \frac{\text{PCA0CPn}}{2^N}$$

**Figure 15.8. N-bit Edge-Aligned PWM Duty Cycle With CEXnPOL = 1 (N = PWM resolution)**

## Center Aligned PWM

When configured for center-aligned mode, a module generates an edge transition at two points for every  $2(N+1)$  PCA clock cycles, where  $N$  is the selected PWM resolution in bits. In center-aligned mode, these two edges are referred to as the “up” and “down” edges. The polarity at the output pin is selectable and can be inverted by setting the appropriate channel bit to 1 in the PCA0POL register.

The generated waveforms are centered about the points where the lower  $N$  bits of the PCA0 counter are zero. The  $(N+1)^{\text{th}}$  bit in the PCA0 counter acts as a selection between up and down edges. In 16-bit mode, a special 17th bit is implemented internally for this purpose. At the center point, the (non-inverted) channel output is low when the  $(N+1)^{\text{th}}$  bit is 0 and high when the  $(N+1)^{\text{th}}$  bit is 1, except for cases of 0% and 100% duty cycle. Prior to inversion, an up edge sets the channel to logic high, and a down edge clears the channel to logic low.

Down edges occur when the  $(N+1)^{\text{th}}$  bit in the PCA0 counter is one and a logical inversion of the value in the module’s PCA0CPn register matches the main PCA0 counter register for the lowest  $N$  bits. For example, with 10-bit PWM, the down edge occurs when the one’s complement of bits 9-0 of the PCA0CPn register match bits 9-0 of the PCA0 counter and bit 10 of the PCA0 counter is 1.

Up edges occur when the  $(N+1)^{\text{th}}$  bit in the PCA0 counter is zero and the lowest  $N$  bits of the module’s PCA0CPn register match the value of  $(\text{PCA0} - 1)$ . For example, with 10-bit PWM, the up edge occurs when bits 9-0 of the PCA0CPn register are one less than bits 9-0 of the PCA0 counter and bit 10 of the PCA0 counter is 0.

An example of the PWM timing in center-aligned mode for two channels is shown here. In this example, the CEX0POL and CEX1POL bits are cleared to 0.

Figure 15.9. Center-Aligned PWM Timing

Figure 15.10 N-bit Center-Aligned PWM Duty Cycle With  $\text{CEXnPOL} = 0$  ( $N = \text{PWM resolution}$ ) on page 143 describes the duty cycle when  $\text{CEXnPOL}$  in the PCA0POL register is cleared to 0. Figure 15.11 N-bit Center-Aligned PWM Duty Cycle With  $\text{CEXnPOL} = 1$  ( $N = \text{PWM resolution}$ ) on page 143 describes the duty cycle when  $\text{CEXnPOL}$  in the PCA0POL register is set to 1. The equations are true only when the lowest  $N$  bits of the PCA0CPn register are not all 0s or all 1s. With  $\text{CEXnPOL}$  equal to zero, 100% duty cycle is produced when the lowest  $N$  bits of PCA0CPn are all 0, and 0% duty cycle is produced when the lowest  $N$  bits of PCA0CPn are all 1. For a given PCA resolution, the unused high bits in the PCA0 counter and the PCA0CPn compare registers are ignored, and only the used bits of the PCA0CPn register determine the duty cycle.

**Note:** Although the PCA0CPn compare register determines the duty cycle, it is not always appropriate for firmware to update this register directly. See the sections on 8 to 11-bit and 16-bit PWM mode for additional details on adjusting duty cycle in the various modes.

$$\text{Duty Cycle} = \frac{2^N - \text{PCA0CPn} - \frac{1}{2}}{2^N}$$

**Figure 15.10. N-bit Center-Aligned PWM Duty Cycle With CEXnPOL = 0 (N = PWM resolution)**

$$\text{Duty Cycle} = \frac{\text{PCA0CPn} + \frac{1}{2}}{2^N}$$

**Figure 15.11. N-bit Center-Aligned PWM Duty Cycle With CEXnPOL = 1 (N = PWM resolution)**

### 15.3.8.1 8 to 11-Bit PWM Modes

Each module can be used independently to generate a pulse width modulated (PWM) output on its associated CEXn pin. The frequency of the output is dependent on the timebase for the PCA counter/timer and the setting of the PWM cycle length (8 through 11-bits). For backwards-compatibility with the 8-bit PWM mode available on other devices, the 8-bit PWM mode operates slightly different than 9 through 11-bit PWM modes.

**Important:** All channels configured for 8 to 11-bit PWM mode use the same cycle length. It is not possible to configure one channel for 8-bit PWM mode and another for 11-bit mode (for example). However, other PCA channels can be configured to Pin Capture, High-Speed Output, Software Timer, Frequency Output, or 16-bit PWM mode independently. Each channel configured for a PWM mode can be individually selected to operate in edge-aligned or center-aligned mode.

#### 8-bit Pulse Width Modulator Mode

In 8-bit PWM mode, the duty cycle is determined by the value of the low byte of the PCA0CPn register (PCA0CPLn). To adjust the duty cycle, PCA0CPLn should not normally be written directly. Instead, the recommendation is to adjust the duty cycle using the high byte of the PCA0CPn register (register PCA0CPHn). This allows seamless updating of the PWM waveform as PCA0CPLn is reloaded automatically with the value stored in PCA0CPHn during the overflow edge (in edge-aligned mode) or the up edge (in center-aligned mode).

Setting the ECOMn and PWMn bits in the PCA0CPMn register and setting the CLSEL bits in register PCA0PWM to 00b enables 8-Bit pulse width modulator mode. If the MATn bit is set to 1, the CCFn flag for the module is set each time a match edge or up edge occurs. The COVF flag in PCA0PWM can be used to detect the overflow (falling edge), which occurs every 256 PCA clock cycles.

#### 9- to 11-bit Pulse Width Modulator Mode

In 9 to 11-bit PWM mode, the duty cycle is determined by the value of the least significant N bits of the PCA0CPn register, where N is the selected PWM resolution.

To adjust the duty cycle, PCA0CPn should not normally be written directly. Instead, the recommendation is to adjust the duty cycle by writing to an “Auto-Reload” register, which is dual-mapped into the PCA0CPHn and PCA0CPLn register locations. The data written to define the duty cycle should be right-justified in the registers. The auto-reload registers are accessed (read or written) when the bit ARSEL in PCA0PWM is set to 1. The capture/compare registers are accessed when ARSEL is set to 0. This allows seamless updating of the PWM waveform, as the PCA0CPn register is reloaded automatically with the value stored in the auto-reload registers during the overflow edge (in edge-aligned mode) or the up edge (in center-aligned mode).

Setting the ECOMn and PWMn bits in the PCA0CPMn register and setting the CLSEL bits in register PCA0PWM to 00b enables 8-Bit pulse width modulator mode. If the MATn bit is set to 1, the CCFn flag for the module is set each time a match edge or up edge occurs. The COVF flag in PCA0PWM can be used to detect the overflow or down edge.

The 9 to 11-bit PWM mode is selected by setting the ECOMn and PWMn bits in the PCA0CPMn register and setting the CLSEL bits in register PCA0PWM to the desired cycle length (other than 8-bits). If the MATn bit is set to 1, the CCFn flag for the module is set each time a match edge or up edge occurs. The COVF flag in PCA0PWM can be used to detect the overflow or down edge.

**Important:** When writing a 16-bit value to the PCA0CPn registers, the low byte should always be written first. Writing to PCA0CPLn clears the ECOMn bit to 0; writing to PCA0CPHn sets ECOMn to 1.

### 15.3.8.2 16-Bit PWM Mode

A PCA module may also be operated in 16-Bit PWM mode. 16-bit PWM mode is independent of the other PWM modes. The entire PCA0CP register is used to determine the duty cycle in 16-bit PWM mode.

To output a varying duty cycle, new value writes should be synchronized with the PCA CCFn match flag to ensure seamless updates.

16-Bit PWM mode is enabled by setting the ECOMn, PWMn, and PWM16n bits in the PCA0CPMn register. For a varying duty cycle, the match interrupt flag should be enabled (ECCFn = 1 AND MATn = 1) to help synchronize the capture/compare register writes. If the MATn bit is set to 1, the CCFn flag for the module is set each time a match edge or up edge occurs. The CF flag in PCA0CN0 can be used to detect the overflow or down edge.

**Important:** When writing a 16-bit value to the PCA0 Capture/Compare registers, the low byte should always be written first. Writing to PCA0CPLn clears the ECOMn bit to 0; writing to PCA0CPHn sets ECOMn to 1.

### 15.3.8.3 Comparator Clear Function

In 8/9/10/11/16-bit PWM modes, the comparator clear function utilizes the Comparator0 output synchronized to the system clock to clear CEXn to logic low for the current PWM cycle. This comparator clear function can be enabled for each PWM channel by setting the CPCEn bits to 1 in the PCA0CLR SFR. When the comparator clear function is disabled, CEXn is unaffected.

The asynchronous Comparator 0 output is logic high when the voltage of CP0+ is greater than CP0– and logic low when the voltage of CP0+ is less than CP0–. The polarity of the Comparator 0 output is used to clear CEXn as follows: when CPCPOL = 0, CEXn is cleared on the falling edge of the Comparator0 output.

Figure 15.12. CEXn with CPCEn = 1, CPCPOL = 0

When CPCPOL = 1, CEXn is cleared on the rising edge of the Comparator0 output.

Figure 15.13. CEXn with CPCEn = 1, CPCPOL = 1

In the PWM cycle following the current cycle, should the Comparator 0 output remain logic low when CPCPOL = 0 or logic high when CPCPOL = 1, CEXn will continue to be cleared.

Figure 15.14. CEXn with CPCEn = 1, CPCPOL = 0

Figure 15.15. CEXn with CPCEn = 1, CPCPOL = 1

## 15.4 PCA0 Control Registers

### 15.4.1 PCA0CN0: PCA Control

Bit	7	6	5	4	3	2	1	0
Name	CF	CR	Reserved			CCF2	CCF1	CCF0
Access	RW	RW	R			RW	RW	RW
Reset	0	0	0x0			0	0	0

SFR Address: 0xD8 (bit-addressable)

Bit	Name	Reset	Access	Description									
7	CF	0	RW	<b>PCA Counter/Timer Overflow Flag.</b> Set by hardware when the PCA Counter/Timer overflows from 0xFFFF to 0x0000. When the Counter/Timer Overflow (CF) interrupt is enabled, setting this bit causes the CPU to vector to the PCA interrupt service routine. This bit is not automatically cleared by hardware and must be cleared by firmware.									
6	CR	0	RW	<b>PCA Counter/Timer Run Control.</b> This bit enables/disables the PCA Counter/Timer. <table border="1"> <thead> <tr> <th>Value</th> <th>Name</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>STOP</td> <td>Stop the PCA Counter/Timer.</td> </tr> <tr> <td>1</td> <td>RUN</td> <td>Start the PCA Counter/Timer running.</td> </tr> </tbody> </table>	Value	Name	Description	0	STOP	Stop the PCA Counter/Timer.	1	RUN	Start the PCA Counter/Timer running.
Value	Name	Description											
0	STOP	Stop the PCA Counter/Timer.											
1	RUN	Start the PCA Counter/Timer running.											
5:3	<i>Reserved</i>	<i>Must write reset value.</i>											
2	CCF2	0	RW	<b>PCA Module 2 Capture/Compare Flag.</b> This bit is set by hardware when a match or capture occurs. When the CCF2 interrupt is enabled, setting this bit causes the CPU to vector to the PCA interrupt service routine. This bit is not automatically cleared by hardware and must be cleared by firmware.									
1	CCF1	0	RW	<b>PCA Module 1 Capture/Compare Flag.</b> This bit is set by hardware when a match or capture occurs. When the CCF1 interrupt is enabled, setting this bit causes the CPU to vector to the PCA interrupt service routine. This bit is not automatically cleared by hardware and must be cleared by firmware.									
0	CCF0	0	RW	<b>PCA Module 0 Capture/Compare Flag.</b> This bit is set by hardware when a match or capture occurs. When the CCF0 interrupt is enabled, setting this bit causes the CPU to vector to the PCA interrupt service routine. This bit is not automatically cleared by hardware and must be cleared by firmware.									

### 15.4.2 PCA0MD: PCA Mode

Bit	7	6	5	4	3	2	1	0
Name	CIDL	Reserved			CPS			ECF
Access	RW	R			RW			RW
Reset	0	0x0			0x0			0
SFR Address: 0xD9								

Bit	Name	Reset	Access	Description
7	CIDL	0	RW	<b>PCA Counter/Timer Idle Control.</b> Specifies PCA behavior when CPU is in Idle Mode.
	Value	Name	Description	
	0	NORMAL	PCA continues to function normally while the system controller is in Idle Mode.	
	1	SUSPEND	PCA operation is suspended while the system controller is in Idle Mode.	
6:4	<i>Reserved</i>	<i>Must write reset value.</i>		
3:1	CPS	0x0	RW	<b>PCA Counter/Timer Pulse Select.</b> These bits select the timebase source for the PCA counter.
	Value	Name	Description	
	0x0	SYSCLK_DIV_12	System clock divided by 12.	
	0x1	SYSCLK_DIV_4	System clock divided by 4.	
	0x2	T0_OVERFLOW	Timer 0 overflow.	
	0x3	ECl	High-to-low transitions on ECl (max rate = system clock divided by 4).	
	0x4	SYSCLK	System clock.	
	0x5	EXTOSC_DIV_8	External clock divided by 8 (synchronized with the system clock).	
	0x6	LFOSC_DIV_8	Low frequency oscillator divided by 8.	
0	ECF	0	RW	<b>PCA Counter/Timer Overflow Interrupt Enable.</b> This bit sets the masking of the PCA Counter/Timer Overflow (CF) interrupt.
	Value	Name	Description	
	0	OVF_INT_DISABLED	Disable the CF interrupt.	
	1	OVF_INT_ENABLED	Enable a PCA Counter/Timer Overflow interrupt request when CF is set.	

### 15.4.3 PCA0PWM: PCA PWM Configuration

Bit	7	6	5	4	3	2	1	0
Name	ARSEL	ECOV	COVF	Reserved		CLSEL		
Access	RW	RW	RW	R		RW		
Reset	0	0	0	0x0		0x0		
SFR Address: 0xF7								

Bit	Name	Reset	Access	Description															
7	ARSEL	0	RW	<p><b>Auto-Reload Register Select.</b></p> <p>This bit selects whether to read and write the normal PCA capture/compare registers (PCA0CPn), or the Auto-Reload registers at the same SFR addresses. This function is used to define the reload value for 9 to 11-bit PWM modes. In all other modes, the Auto-Reload registers have no function.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Name</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>CAPTURE_COMPARE</td> <td>Read/Write Capture/Compare Registers at PCA0CPHn and PCA0CPLn.</td> </tr> <tr> <td>1</td> <td>AUTORELOAD</td> <td>Read/Write Auto-Reload Registers at PCA0CPHn and PCA0CPLn.</td> </tr> </tbody> </table>	Value	Name	Description	0	CAPTURE_COMPARE	Read/Write Capture/Compare Registers at PCA0CPHn and PCA0CPLn.	1	AUTORELOAD	Read/Write Auto-Reload Registers at PCA0CPHn and PCA0CPLn.						
Value	Name	Description																	
0	CAPTURE_COMPARE	Read/Write Capture/Compare Registers at PCA0CPHn and PCA0CPLn.																	
1	AUTORELOAD	Read/Write Auto-Reload Registers at PCA0CPHn and PCA0CPLn.																	
6	ECOV	0	RW	<p><b>Cycle Overflow Interrupt Enable.</b></p> <p>This bit sets the masking of the Cycle Overflow Flag (COVF) interrupt.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Name</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>COVF_MASK_DISABLED</td> <td>COVF will not generate PCA interrupts.</td> </tr> <tr> <td>1</td> <td>COVF_MASK_ENABLED</td> <td>A PCA interrupt will be generated when COVF is set.</td> </tr> </tbody> </table>	Value	Name	Description	0	COVF_MASK_DISABLED	COVF will not generate PCA interrupts.	1	COVF_MASK_ENABLED	A PCA interrupt will be generated when COVF is set.						
Value	Name	Description																	
0	COVF_MASK_DISABLED	COVF will not generate PCA interrupts.																	
1	COVF_MASK_ENABLED	A PCA interrupt will be generated when COVF is set.																	
5	COVF	0	RW	<p><b>Cycle Overflow Flag.</b></p> <p>This bit indicates an overflow of the 8th to 11th bit of the main PCA counter (PCA0). The specific bit used for this flag depends on the setting of the Cycle Length Select bits. The bit can be set by hardware or firmware, but must be cleared by firmware.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Name</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>NO_OVERFLOW</td> <td>No overflow has occurred since the last time this bit was cleared.</td> </tr> <tr> <td>1</td> <td>OVERFLOW</td> <td>An overflow has occurred since the last time this bit was cleared.</td> </tr> </tbody> </table>	Value	Name	Description	0	NO_OVERFLOW	No overflow has occurred since the last time this bit was cleared.	1	OVERFLOW	An overflow has occurred since the last time this bit was cleared.

The ARSEL bit in register PCA0PWM controls which register is accessed.
A write to this register will set the module's ECOM bit to a 1.				

## 16. Serial Peripheral Interface (SPI0)

### 16.1 Introduction

The serial peripheral interface (SPI) module provides access to a flexible, full-duplex synchronous serial bus. The SPI can operate as a master or slave device in both 3-wire or 4-wire modes, and supports multiple masters and slaves on a single SPI bus. The slave-select (NSS) signal can be configured as an input to select the SPI in slave mode, or to disable master mode operation in a multi-master environment, avoiding contention on the SPI bus when more than one master attempts simultaneous data transfers. NSS can also be configured as a firmware-controlled chip-select output in master mode, or disabled to reduce the number of pins required. Additional general purpose port I/O pins can be used to select multiple slave devices in master mode.

Figure 16.1. SPI Block Diagram

### 16.2 Features

The SPI module includes the following features:

- Supports 3- or 4-wire operation in master or slave modes.
- Supports external clock frequencies up to  $\text{SYSCLK} / 2$  in master mode and  $\text{SYSCLK} / 10$  in slave mode.
- Support for four clock phase and polarity options.
- 8-bit dedicated clock rate generator.
- Support for multiple masters on the same data lines.

## 16.3 Functional Description

### 16.3.1 Signals

The SPI interface consists of up to four signals: MOSI, MISO, SCK, and NSS.

**Master Out, Slave In (MOSI):** The MOSI signal is the data output pin when configured as a master device and the data input pin when configured as a slave. It is used to serially transfer data from the master to the slave. Data is transferred on the MOSI pin most-significant bit first. When configured as a master, MOSI is driven from the internal shift register in both 3- and 4-wire mode.

**Master In, Slave Out (MISO):** The MISO signal is the data input pin when configured as a master device and the data output pin when configured as a slave. It is used to serially transfer data from the slave to the master. Data is transferred on the MISO pin most-significant bit first. The MISO pin is placed in a high-impedance state when the SPI module is disabled or when the SPI operates in 4-wire mode as a slave that is not selected. When acting as a slave in 3-wire mode, MISO is always driven from the internal shift register.

**Serial Clock (SCK):** The SCK signal is an output from the master device and an input to slave devices. It is used to synchronize the transfer of data between the master and slave on the MOSI and MISO lines. The SPI module generates this signal when operating as a master and receives it as a slave. The SCK signal is ignored by a SPI slave when the slave is not selected in 4-wire slave mode.

**Slave Select (NSS):** The function of the slave-select (NSS) signal is dependent on the setting of the NSSMD bitfield. There are three possible modes that can be selected with these bits:

- NSSMD[1:0] = 00: 3-Wire Master or 3-Wire Slave Mode: The SPI operates in 3-wire mode, and NSS is disabled. When operating as a slave device, the SPI is always selected in 3-wire mode. Since no select signal is present, the SPI must be the only slave on the bus in 3-wire mode. This is intended for point-to-point communication between a master and a single slave.
- NSSMD[1:0] = 01: 4-Wire Slave or Multi-Master Mode: The SPI operates in 4-wire mode, and NSS is configured as an input. When operating as a slave, NSS selects the SPI device. When operating as a master, a 1-to- 0 transition of the NSS signal disables the master function of the SPI module so that multiple master devices can be used on the same SPI bus.
- NSSMD[1:0] = 1x: 4-Wire Master Mode: The SPI operates in 4-wire mode, and NSS is enabled as an output. The setting of NSSMD0 determines what logic level the NSS pin will output. This configuration should only be used when operating the SPI as a master device.

The setting of NSSMD bits affects the pinout of the device. When in 3-wire master or 3-wire slave mode, the NSS pin will not be mapped by the crossbar. In all other modes, the NSS signal will be mapped to a pin on the device.

Figure 16.2. 4-Wire Connection Diagram

Figure 16.3. 3-Wire Connection Diagram

Figure 16.4. Multi-Master Connection Diagram

### 16.3.2 Master Mode Operation

An SPI master device initiates all data transfers on a SPI bus. It drives the SCK line and controls the speed at which data is transferred. To place the SPI in master mode, the MSTEN bit should be set to 1. Writing a byte of data to the SPInDAT register writes to the transmit buffer. If the SPI shift register is empty, a byte is moved from the transmit buffer into the shift register, and a bi-directional data transfer begins. The SPI module provides the serial clock on SCK, while simultaneously shifting data out of the shift register MSB-first on MOSI and into the shift register MSB-first on MISO. Upon completing a transfer, the data received is moved from the shift register into the receive buffer. If the transmit buffer is not empty, the next byte in the transmit buffer will be moved into the shift register and the next data transfer will begin. If no new data is available in the transmit buffer, the SPI will halt and wait for new data to initiate the next transfer. Bytes that have been received and stored in the receive buffer may be read from the buffer via the SPInDAT register.

### 16.3.3 Slave Mode Operation

When the SPI block is enabled and not configured as a master, it will operate as a SPI slave. As a slave, bytes are shifted in through the MOSI pin and out through the MISO pin by an external master device controlling the SCK signal. A bit counter in the SPI logic counts SCK edges. When 8 bits have been shifted through the shift register, a byte is copied into the receive buffer. Data is read from the receive buffer by reading SPInDAT. A slave device cannot initiate transfers. Data to be transferred to the master device is pre-loaded into the transmit buffer by writing to SPInDAT and will transfer to the shift register on byte boundaries in the order in which they were written to the buffer.

When configured as a slave, SPI0 can be configured for 4-wire or 3-wire operation. In the default, 4-wire slave mode, the NSS signal is routed to a port pin and configured as a digital input. The SPI interface is enabled when NSS is logic 0, and disabled when NSS is logic 1. The internal shift register bit counter is reset on a falling edge of NSS. When operated in 3-wire slave mode, NSS is not mapped to an external port pin through the crossbar. Since there is no way of uniquely addressing the device in 3-wire slave mode, the SPI must be the only slave device present on the bus. It is important to note that in 3-wire slave mode there is no external means of resetting the bit counter that determines when a full byte has been received. The bit counter can only be reset by disabling and re-enabling the SPI module with the SPIEN bit.

### 16.3.4 Clock Phase and Polarity

Four combinations of serial clock phase and polarity can be selected using the clock control bits in the SPInCFG register. The CKPHA bit selects one of two clock phases (edge used to latch the data). The CKPOL bit selects between an active-high or active-low clock. Both master and slave devices must be configured to use the same clock phase and polarity. The SPI module should be disabled (by clearing the SPIEN bit) when changing the clock phase or polarity. Note that CKPHA should be set to 0 on both the master and slave SPI when communicating between two Silicon Labs devices.

Figure 16.5. Master Mode Data/Clock Timing

Figure 16.6. Slave Mode Data/Clock Timing (CKPHA = 0)

Figure 16.7. Slave Mode Data/Clock Timing (CKPHA = 1)

### 16.3.5 Basic Data Transfer

The SPI bus is inherently full-duplex. It sends and receives a single byte on every transfer. The SPI peripheral may be operated on a byte-by-byte basis using the SPInDAT register and the SPIF flag. The method firmware uses to send and receive data through the SPI interface is the same in either mode, but the hardware will react differently.

#### Master Transfers

As an SPI master, all transfers are initiated with a write to SPInDAT, and the SPIF flag will be set by hardware to indicate the end of each transfer. The general method for a single-byte master transfer follows:

1. Write the data to be sent to SPInDAT. The transfer will begin on the bus at this time.
2. Wait for the SPIF flag to generate an interrupt, or poll SPIF until it is set to 1.
3. Read the received data from SPInDAT.
4. Clear the SPIF flag to 0.
5. Repeat the sequence for any additional transfers.

#### Slave Transfers

As a SPI slave, the transfers are initiated by an external master device driving the bus. Slave firmware may anticipate any output data needs by pre-loading the SPInDAT register before the master begins the transfer.

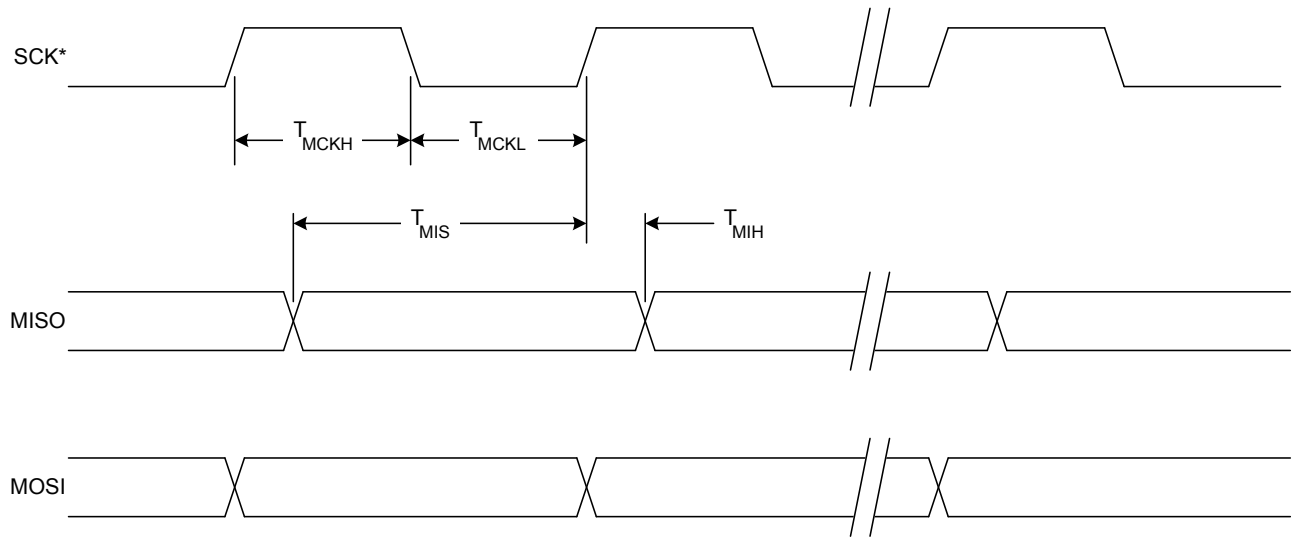

1. Write any data to be sent to SPInDAT. The transfer will not begin until the external master device initiates it.
2. Wait for the SPIF flag to generate an interrupt, or poll SPIF until it is set to 1.
3. Read the received data from SPInDAT.
4. Clear the SPIF flag to 0.
5. Repeat the sequence for any additional transfers.

### 16.3.6 SPI Timing Diagrams

\* SCK is shown for CKPOL = 0. SCK is the opposite polarity for CKPOL = 1.

**Figure 16.8. SPI Master Timing (CKPHA = 0)**

**Table 16.1. SPI Timing Parameters**

Parameter	Description	Min	Max	Units
<b>Master Mode Timing</b>				
$T_{MCKH}$	SCK High Time	$1 \times T_{SYSCLK}$	—	ns
$T_{MCKL}$	SCK Low Time	$1 \times T_{SYSCLK}$	—	ns
$T_{MIS}$	MISO Valid to SCK Shift Edge	$1 \times T_{SYSCLK} + 20$	—	ns
$T_{MIH}$	SCK Shift Edge to MISO Change	0	—	ns
<b>Slave Mode Timing</b>				
$T_{SE}$	NSS Falling to First SCK Edge	$2 \times T_{SYSCLK}$	—	ns
$T_{SD}$	Last SCK Edge to NSS Rising	$2 \times T_{SYSCLK}$	—	ns
$T_{SEZ}$	NSS Falling to MISO Valid	—	$4 \times T_{SYSCLK}$	ns
$T_{SDZ}$	NSS Rising to MISO High-Z	—	$4 \times T_{SYSCLK}$	ns
$T_{CKH}$	SCK High Time	$5 \times T_{SYSCLK}$	—	ns
$T_{CKL}$	SCK Low Time	$5 \times T_{SYSCLK}$	—	ns
$T_{SIS}$	MOSI Valid to SCK Sample Edge	$2 \times T_{SYSCLK}$	—	ns
$T_{SIH}$	SCK Sample Edge to MOSI Change	$2 \times T_{SYSCLK}$	—	ns
$T_{SOH}$	SCK Shift Edge to MISO Change	—	$4 \times T_{SYSCLK}$	ns
$T_{SLH}$	Last SCK Edge to MISO Change (CKPHA = 1 ONLY)	$6 \times T_{SYSCLK}$	$8 \times T_{SYSCLK}$	ns
<b>Note:</b>				
1. $T_{SYSCLK}$ is equal to one period of the device system clock (SYSCLK).				

## 16.4 SPI0 Control Registers

### 16.4.1 SPI0CFG: SPI0 Configuration

Bit	7	6	5	4	3	2	1	0
Name	SPIBSY	MSTEN	CKPHA	CKPOL	SLVSEL	NSSIN	SRMT	RXBMT
Access	R	RW	RW	RW	R	R	R	R
Reset	0	0	0	0	0	1	1	1

SFR Address: 0xA1

Bit	Name	Reset	Access	Description
7	SPIBSY	0	R	<b>SPI Busy.</b> This bit is set to logic 1 when a SPI transfer is in progress (master or slave mode).
6	MSTEN	0	RW	<b>Master Mode Enable.</b>
	Value	Name	Description	
	0	MASTER_DISABLED	Disable master mode. Operate in slave mode.	
	1	MASTER_ENABLED	Enable master mode. Operate as a master.	
5	CKPHA	0	RW	<b>SPI0 Clock Phase.</b>
	Value	Name	Description	
	0	DATA_CENT- TERED_FIRST	Data centered on first edge of SCK period.	
	1	DATA_CEN- TERED_SECOND	Data centered on second edge of SCK period.	
4	CKPOL	0	RW	<b>SPI0 Clock Polarity.</b>
	Value	Name	Description	
	0	IDLE_LOW	SCK line low in idle state.	
	1	IDLE_HIGH	SCK line high in idle state.	
3	SLVSEL	0	R	<b>Slave Selected Flag.</b> This bit is set to logic 1 whenever the NSS pin is low indicating SPI0 is the selected slave. It is cleared to logic 0 when NSS is high (slave not selected). This bit does not indicate the instantaneous value at the NSS pin, but rather a de-glitched version of the pin input.
2	NSSIN	1	R	<b>NSS Instantaneous Pin Input.</b> This bit mimics the instantaneous value that is present on the NSS port pin at the time that the register is read. This input is not de-glitched.
1	SRMT	1	R	<b>Shift Register Empty.</b> This bit will be set to logic 1 when all data has been transferred in/out of the shift register, and there is no new information available to read from the transmit buffer or write to the receive buffer. It returns to logic 0 when a data byte is transferred to the shift register from the transmit buffer or by a transition on SCK.

Bit	Name	Reset	Access	Description
0	RXBMT	1	R	<p><b>Receive Buffer Empty.</b></p> <p>This bit is valid in slave mode only and will be set to logic 1 when the receive buffer has been read and contains no new information. If there is new information available in the receive buffer that has not been read, this bit will return to logic 0. RXBMT = 1 when in Master Mode.</p>
<p>In slave mode, data on MOSI is sampled in the center of each data bit. In master mode, data on MISO is sampled one SYSCLK before the end of each data bit, to provide maximum settling time for the slave device.</p>				

### 16.4.2 SPI0CN0: SPI0 Control

Bit	7	6	5	4	3	2	1	0
Name	SPIF	WCOL	MODF	RXOVRN	NSSMD		TXBMT	SPIEN
Access	RW	RW	RW	RW	RW		R	RW
Reset	0	0	0	0	0x1		1	0
SFR Address: 0xF8 (bit-addressable)								

Bit	Name	Reset	Access	Description															
7	SPIF	0	RW	<p><b>SPI0 Interrupt Flag.</b></p> <p>This bit is set to logic 1 by hardware at the end of a data transfer. If SPI interrupts are enabled, an interrupt will be generated. This bit is not automatically cleared by hardware, and must be cleared by firmware.</p>															
6	WCOL	0	RW	<p><b>Write Collision Flag.</b></p> <p>This bit is set to logic 1 if a write to SPI0DAT is attempted when TXBMT is 0. When this occurs, the write to SPI0DAT will be ignored, and the transmit buffer will not be written. If SPI interrupts are enabled, an interrupt will be generated. This bit is not automatically cleared by hardware, and must be cleared by firmware.</p>															
5	MODF	0	RW	<p><b>Mode Fault Flag.</b></p> <p>This bit is set to logic 1 by hardware when a master mode collision is detected (NSS is low, MSTEN = 1, and NSSMD = 01). If SPI interrupts are enabled, an interrupt will be generated. This bit is not automatically cleared by hardware, and must be cleared by firmware.</p>															
4	RXOVRN	0	RW	<p><b>Receive Overrun Flag.</b></p> <p>This bit is valid for slave mode only and is set to logic 1 by hardware when the receive buffer still holds unread data from a previous transfer and the last bit of the current transfer is shifted into the SPI0 shift register. If SPI interrupts are enabled, an interrupt will be generated. This bit is not automatically cleared by hardware, and must be cleared by firmware.</p>															
3:2	NSSMD	0x1	RW	<p><b>Slave Select Mode.</b></p> <p>Selects between the following NSS operation modes:</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Name</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>3_WIRE</td> <td>3-Wire Slave or 3-Wire Master Mode. NSS signal is not routed to a port pin.</td> </tr> <tr> <td>0x1</td> <td>4_WIRE_SLAVE</td> <td>4-Wire Slave or Multi-Master Mode. NSS is an input to the device.</td> </tr> <tr> <td>0x2</td> <td>4_WIRE_MASTER_NSS_LOW</td> <td>4-Wire Single-Master Mode. NSS is an output and logic low.</td> </tr> <tr> <td>0x3</td> <td>4_WIRE_MASTER_NSS_HIGH</td> <td>4-Wire Single-Master Mode. NSS is an output and logic high.</td> </tr> </tbody> </table>	Value	Name	Description	0x0	3_WIRE	3-Wire Slave or 3-Wire Master Mode. NSS signal is not routed to a port pin.	0x1	4_WIRE_SLAVE	4-Wire Slave or Multi-Master Mode. NSS is an input to the device.	0x2	4_WIRE_MASTER_NSS_LOW	4-Wire Single-Master Mode. NSS is an output and logic low.	0x3	4_WIRE_MASTER_NSS_HIGH	4-Wire Single-Master Mode. NSS is an output and logic high.
Value	Name	Description																	
0x0	3_WIRE	3-Wire Slave or 3-Wire Master Mode. NSS signal is not routed to a port pin.																	
0x1	4_WIRE_SLAVE	4-Wire Slave or Multi-Master Mode. NSS is an input to the device.																	
0x2	4_WIRE_MASTER_NSS_LOW	4-Wire Single-Master Mode. NSS is an output and logic low.																	
0x3	4_WIRE_MASTER_NSS_HIGH	4-Wire Single-Master Mode. NSS is an output and logic high.																	
1	TXBMT	1	R	<p><b>Transmit Buffer Empty.</b></p> <p>This bit will be set to logic 0 when new data has been written to the transmit buffer. When data in the transmit buffer is transferred to the SPI shift register, this bit will be set to logic 1, indicating that it is safe to write a new byte to the transmit buffer.</p>															
0	SPIEN	0	RW	<p><b>SPI0 Enable.</b></p> <table border="1"> <thead> <tr> <th>Value</th> <th>Name</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>DISABLED</td> <td>Disable the SPI module.</td> </tr> <tr> <td>1</td> <td>ENABLED</td> <td>Enable the SPI module.</td> </tr> </tbody> </table>	Value	Name	Description	0	DISABLED	Disable the SPI module.	1	ENABLED	Enable the SPI module.						
Value	Name	Description																	
0	DISABLED	Disable the SPI module.																	
1	ENABLED	Enable the SPI module.																	

### 16.4.3 SPI0CKR: SPI0 Clock Rate

Bit	7	6	5	4	3	2	1	0
Name	SPI0CKR							
Access	RW							
Reset	0x00							
SFR Address: 0xA2								

Bit	Name	Reset	Access	Description
7:0	SPI0CKR	0x00	RW	<p><b>SPI0 Clock Rate.</b></p> <p>These bits determine the frequency of the SCK output when the SPI0 module is configured for master mode operation. The SCK clock frequency is a divided version of the system clock, and is given in the following equation, where SYSCLK is the system clock frequency and SPI0CKR is the 8-bit value held in the SPI0CKR register.</p> $f_{sck} = \text{SYSCLK} / (2 * (\text{SPI0CKR} + 1))$ <p>for <math>0 \leq \text{SPI0CKR} \leq 255</math></p>

### 16.4.4 SPI0DAT: SPI0 Data

Bit	7	6	5	4	3	2	1	0
Name	SPI0DAT							
Access	RW							
Reset	Varies							
SFR Address: 0xA3								

Bit	Name	Reset	Access	Description
7:0	SPI0DAT	Varies	RW	<p><b>SPI0 Transmit and Receive Data.</b></p> <p>The SPI0DAT register is used to transmit and receive SPI0 data. Writing data to SPI0DAT places the data into the transmit buffer and initiates a transfer when in master mode. A read of SPI0DAT returns the contents of the receive buffer.</p>

## 17. System Management Bus / I2C (SMB0)

### 17.1 Introduction

The SMBus I/O interface is a two-wire, bi-directional serial bus. The SMBus is compliant with the System Management Bus Specification, version 1.1, and compatible with the I<sup>2</sup>C serial bus.

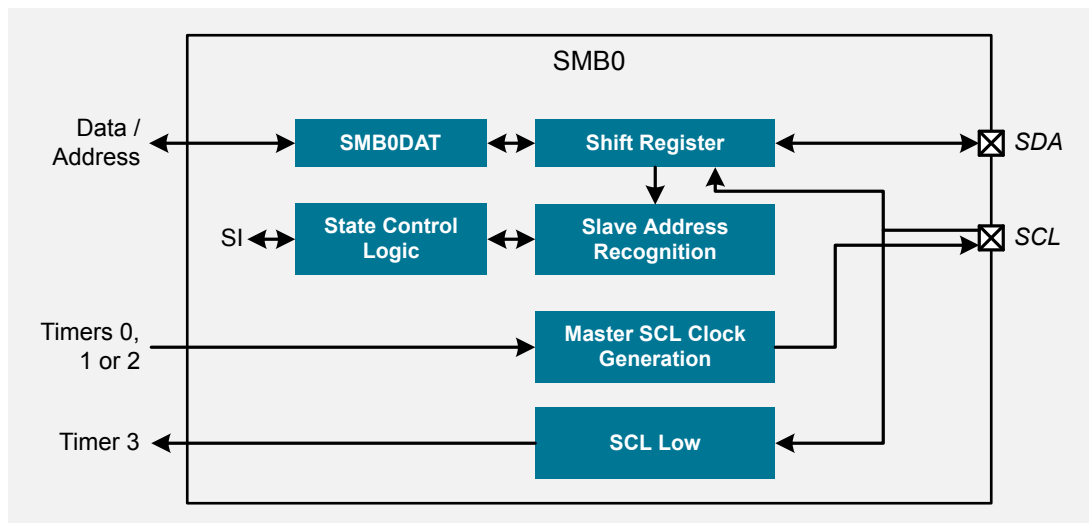

Figure 17.1. SMBus 0 Block Diagram

### 17.2 Features

The SMBus module includes the following features:

- Standard (up to 100 kbps) and Fast (400 kbps) transfer speeds.
- Support for master, slave, and multi-master modes.
- Hardware synchronization and arbitration for multi-master mode.
- Clock low extending (clock stretching) to interface with faster masters.
- Hardware support for 7-bit slave and general call address recognition.
- Firmware support for 10-bit slave address decoding.
- Ability to inhibit all slave states.
- Programmable data setup/hold times.

### 17.3 Functional Description

#### 17.3.1 Supporting Documents

It is assumed the reader is familiar with or has access to the following supporting documents:

- The I<sup>2</sup>C-Bus and How to Use It (including specifications), Philips Semiconductor.
- The I<sup>2</sup>C-Bus Specification—Version 2.0, Philips Semiconductor.
- System Management Bus Specification—Version 1.1, SBS Implementers Forum.

### 17.3.2 SMBus Protocol

The SMBus specification allows any recessive voltage between 3.0 and 5.0 V; different devices on the bus may operate at different voltage levels. However, the maximum voltage on any port pin must conform to the electrical characteristics specifications. The bi-directional SCL (serial clock) and SDA (serial data) lines must be connected to a positive power supply voltage through a pullup resistor or similar circuit. Every device connected to the bus must have an open-drain or open-collector output for both the SCL and SDA lines, so that both are pulled high (recessive state) when the bus is free. The maximum number of devices on the bus is limited only by the requirement that the rise and fall times on the bus not exceed 300 ns and 1000 ns, respectively.

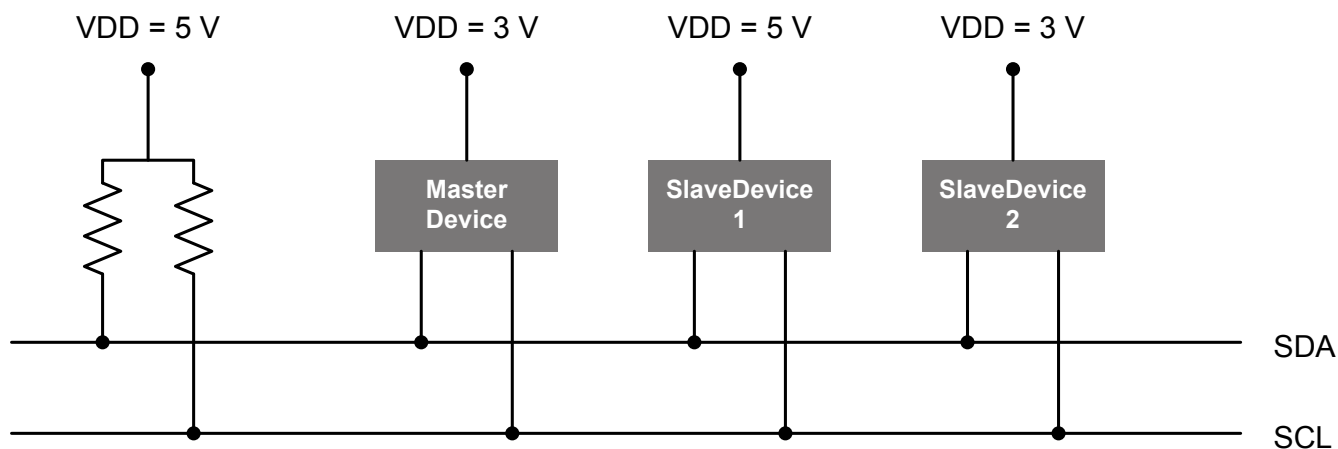

Figure 17.2. Typical SMBus System Connection

Two types of data transfers are possible: data transfers from a master transmitter to an addressed slave receiver (WRITE), and data transfers from an addressed slave transmitter to a master receiver (READ). The master device initiates both types of data transfers and provides the serial clock pulses on SCL. The SMBus interface may operate as a master or a slave, and multiple master devices on the same bus are supported. If two or more masters attempt to initiate a data transfer simultaneously, an arbitration scheme is employed with a single master always winning the arbitration. It is not necessary to specify one device as the Master in a system; any device who transmits a START and a slave address becomes the master for the duration of that transfer.

A typical SMBus transaction consists of a START condition followed by an address byte (Bits7–1: 7-bit slave address; Bit0: R/W direction bit), one or more bytes of data, and a STOP condition. Bytes that are received (by a master or slave) are acknowledged (ACK) with a low SDA during a high SCL (see [Figure 17.3 SMBus Transaction on page 172](#)). If the receiving device does not ACK, the transmitting device will read a NACK (not acknowledge), which is a high SDA during a high SCL.

The direction bit (R/W) occupies the least-significant bit position of the address byte. The direction bit is set to logic 1 to indicate a "READ" operation and cleared to logic 0 to indicate a "WRITE" operation.

All transactions are initiated by a master, with one or more addressed slave devices as the target. The master generates the START condition and then transmits the slave address and direction bit. If the transaction is a WRITE operation from the master to the slave, the master transmits the data a byte at a time waiting for an ACK from the slave at the end of each byte. For READ operations, the slave transmits the data waiting for an ACK from the master at the end of each byte. At the end of the data transfer, the master generates a STOP condition to terminate the transaction and free the bus. [Figure 17.3 SMBus Transaction on page 172](#) illustrates a typical SMBus transaction.

**Figure 17.3. SMBus Transaction**

### Transmitter vs. Receiver

On the SMBus communications interface, a device is the “transmitter” when it is sending an address or data byte to another device on the bus. A device is a “receiver” when an address or data byte is being sent to it from another device on the bus. The transmitter controls the SDA line during the address or data byte. After each byte of address or data information is sent by the transmitter, the receiver sends an ACK or NACK bit during the ACK phase of the transfer, during which time the receiver controls the SDA line.

### Arbitration

A master may start a transfer only if the bus is free. The bus is free after a STOP condition or after the SCL and SDA lines remain high for a specified time (see • [SCL High \(SMBus Free\) Timeout on page 172](#)). In the event that two or more devices attempt to begin a transfer at the same time, an arbitration scheme is employed to force one master to give up the bus. The master devices continue transmitting until one attempts a HIGH while the other transmits a LOW. Since the bus is open-drain, the bus will be pulled LOW. The master attempting the HIGH will detect a LOW SDA and lose the arbitration. The winning master continues its transmission without interruption; the losing master becomes a slave and receives the rest of the transfer if addressed. This arbitration scheme is non-destructive: one device always wins, and no data is lost.

### Clock Low Extension

SMBus provides a clock synchronization mechanism, similar to I<sup>2</sup>C, which allows devices with different speed capabilities to coexist on the bus. A clock-low extension is used during a transfer in order to allow slower slave devices to communicate with faster masters. The slave may temporarily hold the SCL line LOW to extend the clock low period, effectively decreasing the serial clock frequency.

### SCL Low Timeout

If the SCL line is held low by a slave device on the bus, no further communication is possible. Furthermore, the master cannot force the SCL line high to correct the error condition. To solve this problem, the SMBus protocol specifies that devices participating in a transfer must detect any clock cycle held low longer than 25 ms as a “timeout” condition. Devices that have detected the timeout condition must reset the communication no later than 10 ms after detecting the timeout condition.

For the SMBus 0 interface, Timer 3 is used to implement SCL low timeouts. The SCL low timeout feature is enabled by setting the SMB0TOE bit in SMB0CF. The associated timer is forced to reload when SCL is high, and allowed to count when SCL is low. With the associated timer enabled and configured to overflow after 25 ms (and SMB0TOE set), the timer interrupt service routine can be used to reset (disable and re-enable) the SMBus in the event of an SCL low timeout.

### SCL High (SMBus Free) Timeout

The SMBus specification stipulates that if the SCL and SDA lines remain high for more than 50 μs, the bus is designated as free. When the SMB0FTE bit in SMB0CF is set, the bus will be considered free if SCL and SDA remain high for more than 10 SMBus clock source periods (as defined by the timer configured for the SMBus clock source). If the SMBus is waiting to generate a Master START, the START will be generated following this timeout. A clock source is required for free timeout detection, even in a slave-only implementation.

### 17.3.3 Configuring the SMBus Module

The SMBus can operate in both Master and Slave modes. The interface provides timing and shifting control for serial transfers; higher level protocol is determined by user software. The SMBus interface provides the following application-independent features:

- Byte-wise serial data transfers
- Clock signal generation on SCL (Master Mode only) and SDA data synchronization
- Timeout/bus error recognition, as defined by the SMB0CF configuration register
- START/STOP timing, detection, and generation
- Bus arbitration
- Interrupt generation
- Status information
- Optional hardware recognition of slave address and automatic acknowledgement of address/data

SMBus interrupts are generated for each data byte or slave address that is transferred. When hardware acknowledgement is disabled, the point at which the interrupt is generated depends on whether the hardware is acting as a data transmitter or receiver. When a transmitter (i.e., sending address/data, receiving an ACK), this interrupt is generated after the ACK cycle so that software may read the received ACK value; when receiving data (i.e., receiving address/data, sending an ACK), this interrupt is generated before the ACK cycle so that software may define the outgoing ACK value. If hardware acknowledgement is enabled, these interrupts are always generated after the ACK cycle. Interrupts are also generated to indicate the beginning of a transfer when a master (START generated), or the end of a transfer when a slave (STOP detected). Software should read the SMB0CN0 register to find the cause of the SMBus interrupt.

## SMBus Configuration Register

The SMBus Configuration register (SMB0CF) is used to enable the SMBus master and/or slave modes, select the SMBus clock source, and select the SMBus timing and timeout options. When the ENSMB bit is set, the SMBus is enabled for all master and slave events. Slave events may be disabled by setting the INH bit. With slave events inhibited, the SMBus interface will still monitor the SCL and SDA pins; however, the interface will NACK all received addresses and will not generate any slave interrupts. When the INH bit is set, all slave events will be inhibited following the next START (interrupts will continue for the duration of the current transfer).

The SMBCS bit field selects the SMBus clock source, which is used only when operating as a master or when the Free Timeout detection is enabled. When operating as a master, overflows from the selected source determine both the bit rate and the absolute minimum SCL low and high times. The selected clock source may be shared by other peripherals so long as the timer is left running at all times. The selected clock source should typically be configured to overflow at three times the desired bit rate. When the interface is operating as a master (and SCL is not driven or extended by any other devices on the bus), the device will hold the SCL line low for one overflow period, and release it for two overflow periods.  $T_{HIGH}$  is typically twice as large as  $T_{LOW}$ . The actual SCL output may vary due to other devices on the bus (SCL may be extended low by slower slave devices, driven low by contending master devices, or have long ramp times). The SMBus hardware will ensure that once SCL does return high, it reads a logic high state for a minimum of one overflow period.

Figure 17.4. Typical SMBus SCL Generation

Setting the EXTHOLD bit extends the minimum setup and hold times for the SDA line. The minimum SDA setup time defines the absolute minimum time that SDA is stable before SCL transitions from low-to-high. The minimum SDA hold time defines the absolute minimum time that the current SDA value remains stable after SCL transitions from high-to-low. EXTHOLD should be set so that the minimum setup and hold times meet the SMBus Specification requirements of 250 ns and 300 ns, respectively. Setup and hold time extensions are typically necessary for SMBus compliance when SYSCLK is above 10 MHz.

Table 17.1. Minimum SDA Setup and Hold Times

EXTHOLD	Minimum SDA Setup Time	Minimum SDA Hold Time
0	$T_{low} - 4$ system clocks or 1 system clock + s/w delay	3 system clocks
1	11 system clocks	12 system clocks

**Note:** Setup Time for ACK bit transmissions and the MSB of all data transfers. When using software acknowledgment, the s/w delay occurs between the time SMB0DAT or ACK is written and when SI is cleared. Note that if SI is cleared in the same write that defines the outgoing ACK value, s/w delay is zero.

With the SMBTOE bit set, Timer 3 should be configured to overflow after 25 ms in order to detect SCL low timeouts. The SMBus interface will force the associated timer to reload while SCL is high, and allow the timer to count when SCL is low. The timer interrupt service routine should be used to reset SMBus communication by disabling and re-enabling the SMBus. SMBus Free Timeout detection can be enabled by setting the SMBFTE bit. When this bit is set, the bus will be considered free if SDA and SCL remain high for more than 10 SMBus clock source periods.

## SMBus Pin Swap

The SMBus peripheral is assigned to pins using the priority crossbar decoder. By default, the SMBus signals are assigned to port pins starting with SDA on the lower-numbered pin, and SCL on the next available pin. The SWAP bit in the SMBTC register can be set to 1 to reverse the order in which the SMBus signals are assigned.

## SMBus Timing Control

The SDD field in the SMBTC register is used to restrict the detection of a START condition under certain circumstances. In some systems where there is significant mismatch between the impedance or the capacitance on the SDA and SCL lines, it may be possible for SCL to fall after SDA during an address or data transfer. Such an event can cause a false START detection on the bus. These kind of events are not expected in a standard SMBus or I2C-compliant system.

**Note:** In most systems this parameter should not be adjusted, and it is recommended that it be left at its default value.

By default, if the SCL falling edge is detected after the falling edge of SDA (i.e., one SYSCLK cycle or more), the device will detect this as a START condition. The SDD field is used to increase the amount of hold time that is required between SDA and SCL falling before a START is recognized. An additional 2, 4, or 8 SYSCLKs can be added to prevent false START detection in systems where the bus conditions warrant this.

## SMBus Control Register

SMB0CN0 is used to control the interface and to provide status information. The higher four bits of SMB0CN0 (MASTER, TXMODE, STA, and STO) form a status vector that can be used to jump to service routines. MASTER indicates whether a device is the master or slave during the current transfer. TXMODE indicates whether the device is transmitting or receiving data for the current byte.

STA and STO indicate that a START and/or STOP has been detected or generated since the last SMBus interrupt. STA and STO are also used to generate START and STOP conditions when operating as a master. Writing a 1 to STA will cause the SMBus interface to enter Master Mode and generate a START when the bus becomes free (STA is not cleared by hardware after the START is generated). Writing a 1 to STO while in Master Mode will cause the interface to generate a STOP and end the current transfer after the next ACK cycle. If STO and STA are both set (while in Master Mode), a STOP followed by a START will be generated.

The ARBLOST bit indicates that the interface has lost an arbitration. This may occur anytime the interface is transmitting (master or slave). A lost arbitration while operating as a slave indicates a bus error condition. ARBLOST is cleared by hardware each time SI is cleared.

The SI bit (SMBus Interrupt Flag) is set at the beginning and end of each transfer, after each byte frame, or when an arbitration is lost.

**Note:** The SMBus interface is stalled while SI is set; if SCL is held low at this time, the bus is stalled until software clears SI.

## Hardware ACK Generation

When the EHACK bit in register SMB0ADM is set to 1, automatic slave address recognition and ACK generation is enabled. As a receiver, the value currently specified by the ACK bit will be automatically sent on the bus during the ACK cycle of an incoming data byte. As a transmitter, reading the ACK bit indicates the value received on the last ACK cycle. The ACKRQ bit is not used when hardware ACK generation is enabled. If a received slave address is NACKed by hardware, further slave events will be ignored until the next START is detected, and no interrupt will be generated.

**Table 17.2. Sources for Hardware Changes to SMB0CN0**

Bit	Set by Hardware When:	Cleared by Hardware When:
MASTER	A START is generated.	A STOP is generated. Arbitration is lost.
TXMODE	START is generated. SMB0DAT is written before the start of an SMBus frame.	A START is detected. Arbitration is lost. SMB0DAT is not written before the start of an SMBus frame.
STA	A START followed by an address byte is received.	Must be cleared by software.
STO	A STOP is detected while addressed as a slave. Arbitration is lost due to a detected STOP.	A pending STOP is generated.
ACKRQ	A byte has been received and an ACK response value is needed (only when hardware ACK is not enabled).	After each ACK cycle.
ARBLOST	A repeated START is detected as a MASTER when STA is low (unwanted repeated START). SCL is sensed low while attempting to generate a STOP or repeated START condition. SDA is sensed low while transmitting a 1 (excluding ACK bits).	Each time SIn is cleared.
ACK	The incoming ACK value is low (ACKNOWLEDGE).	The incoming ACK value is high (NOT ACKNOWLEDGE).
SI	A START has been generated. Lost arbitration. A byte has been transmitted and an ACK/NACK received. A byte has been received. A START or repeated START followed by a slave address + R/W has been received. A STOP has been received.	Must be cleared by software.

## Hardware Slave Address Recognition

The SMBus hardware has the capability to automatically recognize incoming slave addresses and send an ACK without software intervention. Automatic slave address recognition is enabled by setting the EHACK bit in register SMB0ADM to 1. This will enable both automatic slave address recognition and automatic hardware ACK generation for received bytes (as a master or slave).

The registers used to define which address(es) are recognized by the hardware are the SMBus Slave Address register and the SMBus Slave Address Mask register. A single address or range of addresses (including the General Call Address 0x00) can be specified using these two registers. The most-significant seven bits of the two registers are used to define which addresses will be ACKed. A 1 in a bit of the slave address mask SLVM enables a comparison between the received slave address and the hardware's slave address SLV for that bit. A 0 in a bit of the slave address mask means that bit will be treated as a "don't care" for comparison purposes. In this case, either a 1 or a 0 value are acceptable on the incoming slave address. Additionally, if the GC bit in register SMB0ADR is set to 1, hardware will recognize the General Call Address (0x00).

**Table 17.3. Hardware Address Recognition Examples (EHACK=1)**

Hardware Slave Address SLV	Slave Address Mask SLVM	GC bit	Slave Addresses Recognized by Hardware
0x34	0x7F	0	0x34
0x34	0x7F	1	0x34, 0x00 (General Call)
0x34	0x7E	0	0x34, 0x35
0x34	0x7E	1	0x34, 0x35, 0x00 (General Call)
0x70	0x73	0	0x70, 0x74, 0x78, 0x7C

**Note:** These addresses must be shifted to the left by one bit when writing to the SMB0ADR register.

## Software ACK Generation

In general, it is recommended for applications to use hardware ACK and address recognition. In some cases it may be desirable to drive ACK generation and address recognition from firmware. When the EHACK bit in register SMB0ADM is cleared to 0, the firmware on the device must detect incoming slave addresses and ACK or NACK the slave address and incoming data bytes. As a receiver, writing the ACK bit defines the outgoing ACK value; as a transmitter, reading the ACK bit indicates the value received during the last ACK cycle. ACKRQ is set each time a byte is received, indicating that an outgoing ACK value is needed. When ACKRQ is set, software should write the desired outgoing value to the ACK bit before clearing SI. A NACK will be generated if software does not write the ACK bit before clearing SI. SDA will reflect the defined ACK value immediately following a write to the ACK bit; however SCL will remain low until SI is cleared. If a received slave address is not acknowledged, further slave events will be ignored until the next START is detected.

## SMBus Data Register

The SMBus Data register SMB0DAT holds a byte of serial data to be transmitted or one that has just been received. Software may safely read or write to the data register when the SI flag is set. Software should not attempt to access the SMB0DAT register when the SMBus is enabled and the SI flag is cleared to logic 0.

**Note:** Certain device families have a transmit and receive buffer interface which is accessed by reading and writing the SMB0DAT register. To promote software portability between devices with and without this buffer interface it is recommended that SMB0DAT not be used as a temporary storage location. On buffer-enabled devices, writing the register multiple times will push multiple bytes into the transmit FIFO.

### 17.3.4 Operational Modes

The SMBus interface may be configured to operate as master and/or slave. At any particular time, it will be operating in one of the following four modes: Master Transmitter, Master Receiver, Slave Transmitter, or Slave Receiver. The SMBus interface enters Master Mode any time a START is generated, and remains in Master Mode until it loses an arbitration or generates a STOP. An SMBus interrupt is generated at the end of all SMBus byte frames. The position of the ACK interrupt when operating as a receiver depends on whether hardware ACK generation is enabled. As a receiver, the interrupt for an ACK occurs before the ACK with hardware ACK generation disabled, and after the ACK when hardware ACK generation is enabled. As a transmitter, interrupts occur after the ACK, regardless of whether hardware ACK generation is enabled or not.

### Master Write Sequence

During a write sequence, an SMBus master writes data to a slave device. The master in this transfer will be a transmitter during the address byte, and a transmitter during all data bytes. The SMBus interface generates the START condition and transmits the first byte containing the address of the target slave and the data direction bit. In this case the data direction bit (R/W) will be logic 0 (WRITE). The master then transmits one or more bytes of serial data. After each byte is transmitted, an acknowledge bit is generated by the slave. The transfer is ended when the STO bit is set and a STOP is generated. The interface will switch to Master Receiver Mode if SMB0DAT is not written following a Master Transmitter interrupt. [Figure 17.5 Typical Master Write Sequence on page 178](#) shows a typical master write sequence as it appears on the bus, and [Figure 17.6 Master Write Sequence State Diagram \(EHACK = 1\) on page 179](#) shows the corresponding firmware state machine. Two transmit data bytes are shown, though any number of bytes may be transmitted. Notice that all of the “data byte transferred” interrupts occur after the ACK cycle in this mode, regardless of whether hardware ACK generation is enabled.

**Figure 17.5. Typical Master Write Sequence**

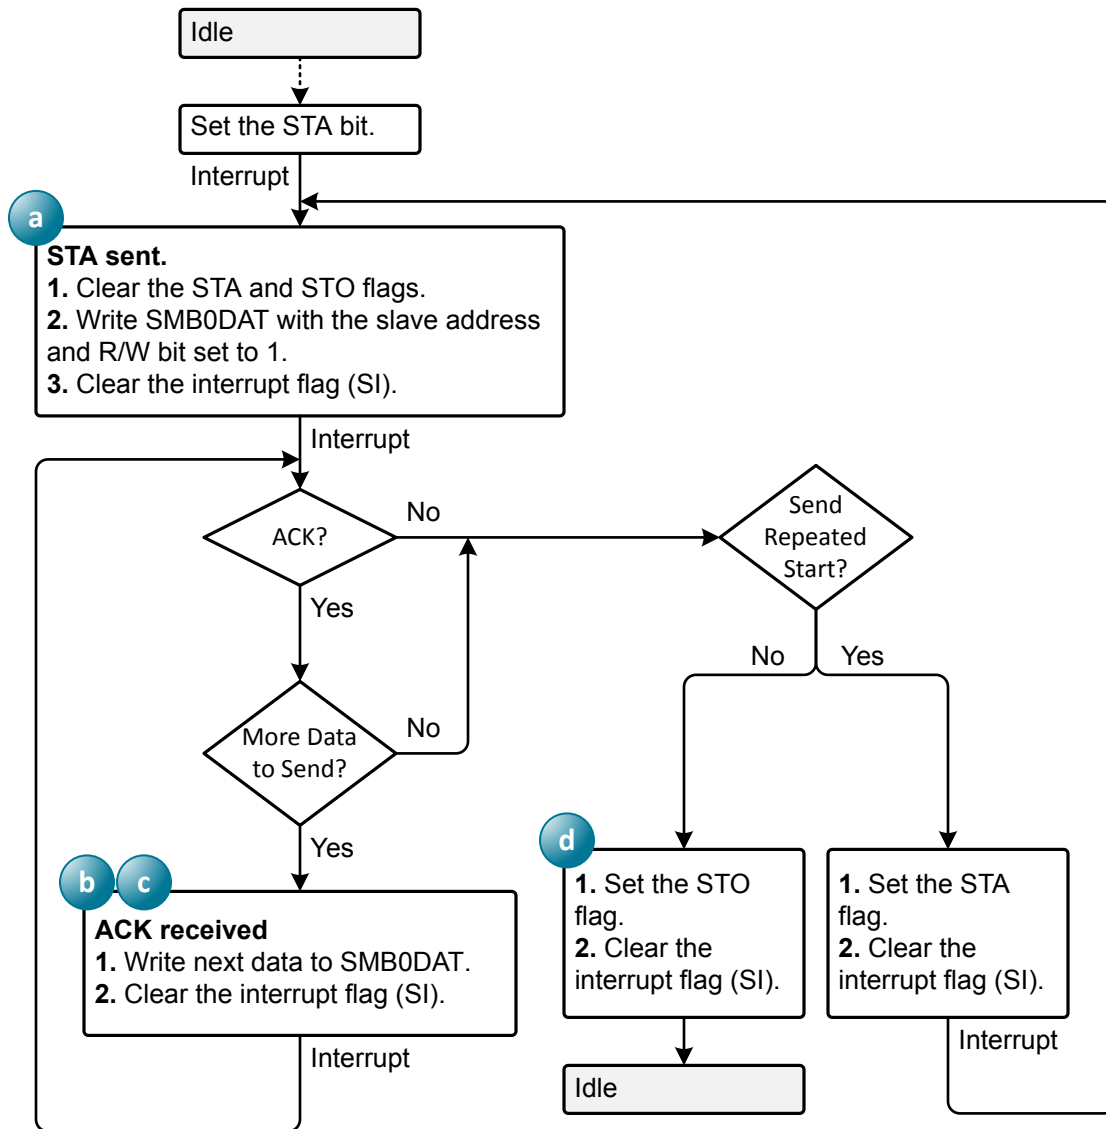

Figure 17.6. Master Write Sequence State Diagram (EHACK = 1)

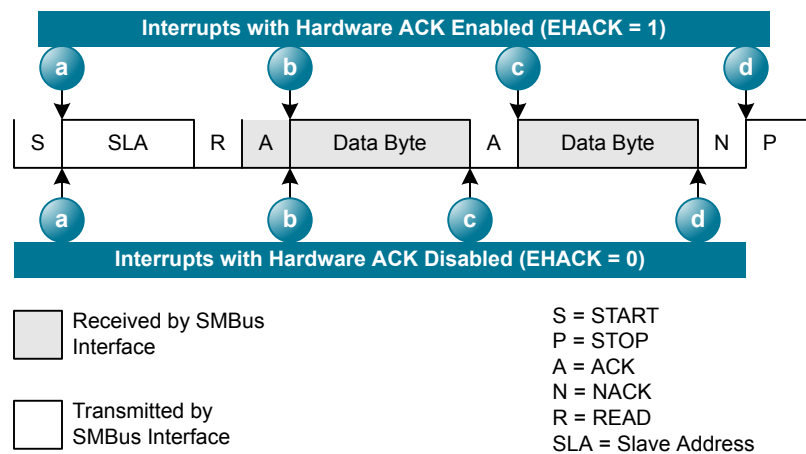

### Master Read Sequence

During a read sequence, an SMBus master reads data from a slave device. The master in this transfer will be a transmitter during the address byte, and a receiver during all data bytes. The SMBus interface generates the START condition and transmits the first byte containing the address of the target slave and the data direction bit. In this case the data direction bit (R/W) will be logic 1 (READ). Serial data is then received from the slave on SDA while the SMBus outputs the serial clock. The slave transmits one or more bytes of serial data.

If hardware ACK generation is disabled, the ACKRQ is set to 1 and an interrupt is generated after each received byte. Software must write the ACK bit at that time to ACK or NACK the received byte.

With hardware ACK generation enabled, the SMBus hardware will automatically generate the ACK/NACK, and then post the interrupt. It is important to note that the appropriate ACK or NACK value should be set up by the software prior to receiving the byte when hardware ACK generation is enabled.

Writing a 1 to the ACK bit generates an ACK; writing a 0 generates a NACK. Software should write a 0 to the ACK bit for the last data transfer, to transmit a NACK. The interface exits Master Receiver Mode after the STO bit is set and a STOP is generated. The interface will switch to Master Transmitter Mode if SMB0DAT is written while an active Master Receiver. [Figure 17.7 Typical Master Read Sequence on page 180](#) shows a typical master read sequence as it appears on the bus, and [Figure 17.8 Master Read Sequence State Diagram \(EHACK = 1\) on page 181](#) shows the corresponding firmware state machine. Two received data bytes are shown, though any number of bytes may be received. Notice that the "data byte transferred" interrupts occur at different places in the sequence, depending on whether hardware ACK generation is enabled. The interrupt occurs before the ACK with hardware ACK generation disabled, and after the ACK when hardware ACK generation is enabled.

**Figure 17.7. Typical Master Read Sequence**

Figure 17.8. Master Read Sequence State Diagram (EHACK = 1)

### Slave Write Sequence

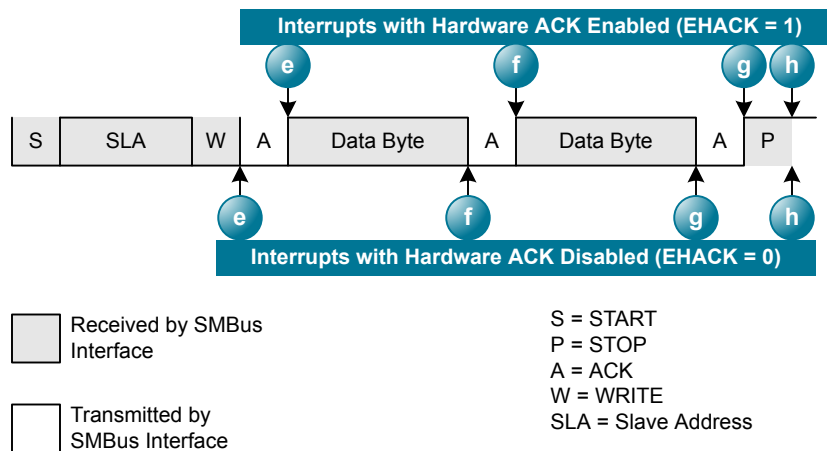

During a write sequence, an SMBus master writes data to a slave device. The slave in this transfer will be a receiver during the address byte, and a receiver during all data bytes. When slave events are enabled (INH = 0), the interface enters Slave Receiver Mode when a START followed by a slave address and direction bit (WRITE in this case) is received. If hardware ACK generation is disabled, upon entering Slave Receiver Mode, an interrupt is generated and the ACKRQ bit is set. The software must respond to the received slave address with an ACK, or ignore the received slave address with a NACK. If hardware ACK generation is enabled, the hardware will apply the ACK for a slave address which matches the criteria set up by SMB0ADR and SMB0ADM. The interrupt will occur after the ACK cycle.

If the received slave address is ignored (by software or hardware), slave interrupts will be inhibited until the next START is detected. If the received slave address is acknowledged, zero or more data bytes are received.

If hardware ACK generation is disabled, the ACKRQ is set to 1 and an interrupt is generated after each received byte. Software must write the ACK bit at that time to ACK or NACK the received byte.

With hardware ACK generation enabled, the SMBus hardware will automatically generate the ACK/NACK, and then post the interrupt. It is important to note that the appropriate ACK or NACK value should be set up by the software prior to receiving the byte when hardware ACK generation is enabled.

The interface exits Slave Receiver Mode after receiving a STOP. The interface will switch to Slave Transmitter Mode if SMB0DAT is written while an active Slave Receiver. [Figure 17.9 Typical Slave Write Sequence on page 182](#) shows a typical slave write sequence as it appears on the bus. The corresponding firmware state diagram (combined with the slave read sequence) is shown in [Figure 17.10 Slave State Diagram \(EHACK = 1\) on page 183](#). Two received data bytes are shown, though any number of bytes may be received. Notice that the "data byte transferred" interrupts occur at different places in the sequence, depending on whether hardware ACK generation is enabled. The interrupt occurs before the ACK with hardware ACK generation disabled, and after the ACK when hardware ACK generation is enabled.

**Figure 17.9. Typical Slave Write Sequence**

Figure 17.10. Slave State Diagram (EHACK = 1)

### Slave Read Sequence

During a read sequence, an SMBus master reads data from a slave device. The slave in this transfer will be a receiver during the address byte, and a transmitter during all data bytes. When slave events are enabled (INH = 0), the interface enters Slave Receiver Mode (to receive the slave address) when a START followed by a slave address and direction bit (READ in this case) is received. If hardware ACK generation is disabled, upon entering Slave Receiver Mode, an interrupt is generated and the ACKRQ bit is set. The software must respond to the received slave address with an ACK, or ignore the received slave address with a NACK. If hardware ACK generation is enabled, the hardware will apply the ACK for a slave address which matches the criteria set up by SMB0ADR and SMB0ADM. The interrupt will occur after the ACK cycle.

If the received slave address is ignored (by software or hardware), slave interrupts will be inhibited until the next START is detected. If the received slave address is acknowledged, zero or more data bytes are transmitted. If the received slave address is acknowledged, data should be written to SMB0DAT to be transmitted. The interface enters slave transmitter mode, and transmits one or more bytes of data. After each byte is transmitted, the master sends an acknowledge bit; if the acknowledge bit is an ACK, SMB0DAT should be written with the next data byte. If the acknowledge bit is a NACK, SMB0DAT should not be written to before SI is cleared (an error condition may be generated if SMB0DAT is written following a received NACK while in slave transmitter mode). The interface exits slave transmitter mode after receiving a STOP. The interface will switch to slave receiver mode if SMB0DAT is not written following a Slave Transmitter interrupt. Figure 17.11 Typical Slave Read Sequence on page 184 shows a typical slave read sequence as it appears on the bus. The corresponding firmware state diagram (combined with the slave read sequence) is shown in Figure 17.10 Slave State Diagram (EHACK = 1) on page 183. Two transmitted data bytes are shown, though any number of bytes may be transmitted. Notice that all of the “data byte transferred” interrupts occur after the ACK cycle in this mode, regardless of whether hardware ACK generation is enabled.

**Figure 17.11. Typical Slave Read Sequence**

## 17.4 SMB0 Control Registers

### 17.4.1 SMB0CF: SMBus 0 Configuration

Bit	7	6	5	4	3	2	1	0
Name	ENSMB	INH	BUSY	EXTHOLD	SMBTOE	SMBFTE	SMBCS	
Access	RW	RW	R	RW	RW	RW	RW	
Reset	0	0	0	0	0	0	0x0	

SFR Address: 0xC1

Bit	Name	Reset	Access	Description															
7	ENSMB	0	RW	<b>SMBus Enable.</b>  This bit enables the SMBus interface when set to 1. When enabled, the interface constantly monitors the SDA and SCL pins.															
6	INH	0	RW	<b>SMBus Slave Inhibit.</b>  When this bit is set to logic 1, the SMBus does not generate an interrupt when slave events occur. This effectively removes the SMBus slave from the bus. Master Mode interrupts are not affected.															
5	BUSY	0	R	<b>SMBus Busy Indicator.</b>  This bit is set to logic 1 by hardware when a transfer is in progress. It is cleared to logic 0 when a STOP or free-timeout is sensed.															
4	EXTHOLD	0	RW	<b>SMBus Setup and Hold Time Extension Enable.</b>  This bit controls the SDA setup and hold times.  <table border="1"> <thead> <tr> <th>Value</th> <th>Name</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>DISABLED</td> <td>Disable SDA extended setup and hold times.</td> </tr> <tr> <td>1</td> <td>ENABLED</td> <td>Enable SDA extended setup and hold times.</td> </tr> </tbody> </table>	Value	Name	Description	0	DISABLED	Disable SDA extended setup and hold times.	1	ENABLED	Enable SDA extended setup and hold times.						
Value	Name	Description																	
0	DISABLED	Disable SDA extended setup and hold times.																	
1	ENABLED	Enable SDA extended setup and hold times.																	
3	SMBTOE	0	RW	<b>SMBus SCL Timeout Detection Enable.</b>  This bit enables SCL low timeout detection. If set to logic 1, the SMBus forces Timer 3 to reload while SCL is high and allows Timer 3 to count when SCL goes low. If Timer 3 is configured to Split Mode, only the High Byte of the timer is held in reload while SCL is high. Timer 3 should be programmed to generate interrupts at 25 ms, and the Timer 3 interrupt service routine should reset SMBus communication.															
2	SMBFTE	0	RW	<b>SMBus Free Timeout Detection Enable.</b>  When this bit is set to logic 1, the bus will be considered free if SCL and SDA remain high for more than 10 SMBus clock source periods.															
1:0	SMBCS	0x0	RW	<b>SMBus Clock Source Selection.</b>  This field selects the SMBus clock source, which is used to generate the SMBus bit rate. See the SMBus clock timing section for additional details.  <table border="1"> <thead> <tr> <th>Value</th> <th>Name</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>TIMER0</td> <td>Timer 0 Overflow.</td> </tr> <tr> <td>0x1</td> <td>TIMER1</td> <td>Timer 1 Overflow.</td> </tr> <tr> <td>0x2</td> <td>TIMER2_HIGH</td> <td>Timer 2 High Byte Overflow.</td> </tr> <tr> <td>0x3</td> <td>TIMER2_LOW</td> <td>Timer 2 Low Byte Overflow.</td> </tr> </tbody> </table>	Value	Name	Description	0x0	TIMER0	Timer 0 Overflow.	0x1	TIMER1	Timer 1 Overflow.	0x2	TIMER2_HIGH	Timer 2 High Byte Overflow.	0x3	TIMER2_LOW	Timer 2 Low Byte Overflow.
Value	Name	Description																	
0x0	TIMER0	Timer 0 Overflow.																	
0x1	TIMER1	Timer 1 Overflow.																	
0x2	TIMER2_HIGH	Timer 2 High Byte Overflow.																	
0x3	TIMER2_LOW	Timer 2 Low Byte Overflow.																	

### 17.4.2 SMB0TC: SMBus 0 Timing and Pin Control

Bit	7	6	5	4	3	2	1	0	
Name	SWAP	Reserved					SDD		
Access	RW	R					RW		
Reset	0	0x00					0x0		
SFR Address: 0xAC									

Bit	Name	Reset	Access	Description															
7	SWAP	0	RW	<p><b>SMBus Swap Pins.</b></p> <p>This bit swaps the order of the SMBus pins on the crossbar.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Name</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>SDA_LOW_PIN</td> <td>SDA is mapped to the lower-numbered port pin, and SCL is mapped to the higher-numbered port pin.</td> </tr> <tr> <td>1</td> <td>SDA_HIGH_PIN</td> <td>SCL is mapped to the lower-numbered port pin, and SDA is mapped to the higher-numbered port pin.</td> </tr> </tbody> </table>	Value	Name	Description	0	SDA_LOW_PIN	SDA is mapped to the lower-numbered port pin, and SCL is mapped to the higher-numbered port pin.	1	SDA_HIGH_PIN	SCL is mapped to the lower-numbered port pin, and SDA is mapped to the higher-numbered port pin.						
Value	Name	Description																	
0	SDA_LOW_PIN	SDA is mapped to the lower-numbered port pin, and SCL is mapped to the higher-numbered port pin.																	
1	SDA_HIGH_PIN	SCL is mapped to the lower-numbered port pin, and SDA is mapped to the higher-numbered port pin.																	
6:2	<i>Reserved</i>	<i>Must write reset value.</i>																	
1:0	SDD	0x0	RW	<p><b>SMBus Start Detection Window.</b></p> <p>These bits increase the hold time requirement between SDA falling and SCL falling for START detection.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Name</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>NONE</td> <td>No additional hold time window (0-1 SYSCCLK).</td> </tr> <tr> <td>0x1</td> <td>ADD_2_SYSCCLKS</td> <td>Increase hold time window to 2-3 SYSCCLKs.</td> </tr> <tr> <td>0x2</td> <td>ADD_4_SYSCCLKS</td> <td>Increase hold time window to 4-5 SYSCCLKs.</td> </tr> <tr> <td>0x3</td> <td>ADD_8_SYSCCLKS</td> <td>Increase hold time window to 8-9 SYSCCLKs.</td> </tr> </tbody> </table>	Value	Name	Description	0x0	NONE	No additional hold time window (0-1 SYSCCLK).	0x1	ADD_2_SYSCCLKS	Increase hold time window to 2-3 SYSCCLKs.	0x2	ADD_4_SYSCCLKS	Increase hold time window to 4-5 SYSCCLKs.	0x3	ADD_8_SYSCCLKS	Increase hold time window to 8-9 SYSCCLKs.
Value	Name	Description																	
0x0	NONE	No additional hold time window (0-1 SYSCCLK).																	
0x1	ADD_2_SYSCCLKS	Increase hold time window to 2-3 SYSCCLKs.																	
0x2	ADD_4_SYSCCLKS	Increase hold time window to 4-5 SYSCCLKs.																	
0x3	ADD_8_SYSCCLKS	Increase hold time window to 8-9 SYSCCLKs.																	

### 17.4.3 SMB0CN0: SMBus 0 Control

Bit	7	6	5	4	3	2	1	0
Name	MASTER	TXMODE	STA	STO	ACKRQ	ARBLOST	ACK	SI
Access	R	R	RW	RW	R	R	RW	RW
Reset	0	0	0	0	0	0	0	0

SFR Address: 0xC0 (bit-addressable)

Bit	Name	Reset	Access	Description									
7	MASTER	0	R	<p><b>SMBus Master/Slave Indicator.</b></p> <p>This read-only bit indicates when the SMBus is operating as a master.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Name</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>SLAVE</td> <td>SMBus operating in slave mode.</td> </tr> <tr> <td>1</td> <td>MASTER</td> <td>SMBus operating in master mode.</td> </tr> </tbody> </table>	Value	Name	Description	0	SLAVE	SMBus operating in slave mode.	1	MASTER	SMBus operating in master mode.
Value	Name	Description											
0	SLAVE	SMBus operating in slave mode.											
1	MASTER	SMBus operating in master mode.											
6	TXMODE	0	R	<p><b>SMBus Transmit Mode Indicator.</b></p> <p>This read-only bit indicates when the SMBus is operating as a transmitter.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Name</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>RECEIVER</td> <td>SMBus in Receiver Mode.</td> </tr> <tr> <td>1</td> <td>TRANSMITTER</td> <td>SMBus in Transmitter Mode.</td> </tr> </tbody> </table>	Value	Name	Description	0	RECEIVER	SMBus in Receiver Mode.	1	TRANSMITTER	SMBus in Transmitter Mode.
Value	Name	Description											
0	RECEIVER	SMBus in Receiver Mode.											
1	TRANSMITTER	SMBus in Transmitter Mode.											
5	STA	0	RW	<p><b>SMBus Start Flag.</b></p> <p>When reading STA, a '1' indicates that a start or repeated start condition was detected on the bus.</p> <p>Writing a '1' to the STA bit initiates a start or repeated start on the bus.</p>									
4	STO	0	RW	<p><b>SMBus Stop Flag.</b></p> <p>When reading STO, a '1' indicates that a stop condition was detected on the bus (in slave mode) or is pending (in master mode).</p> <p>When acting as a master, writing a '1' to the STO bit initiates a stop condition on the bus. This bit is cleared by hardware.</p>									
3	ACKRQ	0	R	<p><b>SMBus Acknowledge Request.</b></p> <table border="1"> <thead> <tr> <th>Value</th> <th>Name</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>NOT_SET</td> <td>No ACK requested.</td> </tr> <tr> <td>1</td> <td>REQUESTED</td> <td>ACK requested.</td> </tr> </tbody> </table>	Value	Name	Description	0	NOT_SET	No ACK requested.	1	REQUESTED	ACK requested.
Value	Name	Description											
0	NOT_SET	No ACK requested.											
1	REQUESTED	ACK requested.											
2	ARBLOST	0	R	<p><b>SMBus Arbitration Lost Indicator.</b></p> <table border="1"> <thead> <tr> <th>Value</th> <th>Name</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>NOT_SET</td> <td>No arbitration error.</td> </tr> <tr> <td>1</td> <td>ERROR</td> <td>Arbitration error occurred.</td> </tr> </tbody> </table>	Value	Name	Description	0	NOT_SET	No arbitration error.	1	ERROR	Arbitration error occurred.
Value	Name	Description											
0	NOT_SET	No arbitration error.											
1	ERROR	Arbitration error occurred.											
1	ACK	0	RW	<p><b>SMBus Acknowledge.</b></p> <p>When read as a master, the ACK bit indicates whether an ACK (1) or NACK (0) is received during the most recent byte transfer.</p> <p>As a slave, this bit should be written to send an ACK (1) or NACK (0) to a master request. Note that the logic level of the ACK bit on the SMBus interface is inverted from the logic of the register ACK bit.</p>									

Bit	Name	Reset	Access	Description
0	SI	0	RW	<b>SMBus Interrupt Flag.</b>  This bit is set by hardware to indicate that the current SMBus state machine operation (such as writing a data or address byte) is complete, and the hardware needs additional control from the firmware to proceed. While SI is set, SCL is held low and SMBus is stalled. SI must be cleared by firmware. Clearing SI initiates the next SMBus state machine operation.

#### 17.4.4 SMB0ADR: SMBus 0 Slave Address

Bit	7	6	5	4	3	2	1	0
Name	SLV							GC
Access	RW							RW
Reset	0x00							0
SFR Address: 0xD7								

Bit	Name	Reset	Access	Description
7:1	SLV	0x00	RW	<b>SMBus Hardware Slave Address.</b>  Defines the SMBus Slave Address(es) for automatic hardware acknowledgement. Only address bits which have a 1 in the corresponding bit position in SLVM are checked against the incoming address. This allows multiple addresses to be recognized.
0	GC	0	RW	<b>General Call Address Enable.</b>  When hardware address recognition is enabled (EHACK = 1), this bit will determine whether the General Call Address (0x00) is also recognized by hardware.
	Value	Name	Description	
	0	IGNORED	General Call Address is ignored.	
	1	RECOGNIZED	General Call Address is recognized.	

#### 17.4.5 SMB0ADM: SMBus 0 Slave Address Mask

Bit	7	6	5	4	3	2	1	0
Name	SLVM							EHACK
Access	RW							RW
Reset	0x7F							0
SFR Address: 0xD6								

Bit	Name	Reset	Access	Description
7:1	SLVM	0x7F	RW	<b>SMBus Slave Address Mask.</b> Defines which bits of register SMB0ADR are compared with an incoming address byte, and which bits are ignored. Any bit set to 1 in SLVM enables comparisons with the corresponding bit in SLV. Bits set to 0 are ignored (can be either 0 or 1 in the incoming address).
0	EHACK	0	RW	<b>Hardware Acknowledge Enable.</b> Enables hardware acknowledgement of slave address and received data bytes.
	Value	Name	Description	
	0	ADR_ACK_MANUAL	Firmware must manually acknowledge all incoming address and data bytes.	
	1	ADR_ACK_AUTOMAT-IC	Automatic slave address recognition and hardware acknowledge is enabled.	

#### 17.4.6 SMB0DAT: SMBus 0 Data

Bit	7	6	5	4	3	2	1	0
Name	SMB0DAT							
Access	RW							
Reset	0x00							
SFR Address: 0xC2								

Bit	Name	Reset	Access	Description
7:0	SMB0DAT	0x00	RW	<b>SMBus 0 Data.</b> The SMB0DAT register contains a byte of data to be transmitted on the SMBus serial interface or a byte that has just been received on the SMBus serial interface. The CPU can safely read from or write to this register whenever the SI serial interrupt flag is set to logic 1. The serial data in the register remains stable as long as the SI flag is set. When the SI flag is not set, the system may be in the process of shifting data in/out and the CPU should not attempt to access this register.

## 18. Timers (Timer0, Timer1, Timer2, and Timer3)

### 18.1 Introduction

Four counter/timers are included in the device: two are 16-bit counter/timers compatible with those found in the standard 8051, and two are 16-bit auto-reload timers for timing peripherals or for general purpose use. These timers can be used to measure time intervals, count external events and generate periodic interrupt requests. Timer 0 and Timer 1 are nearly identical and have four primary modes of operation. Timer 2 and Timer 3 are also identical and offer both 16-bit and split 8-bit timer functionality with auto-reload capabilities. Timer 2 and Timer 3 both offer a capture function, but are different in their system-level connections. Timer 2 is capable of performing a capture function on an external signal input routed through the crossbar, while the Timer 3 capture is dedicated to the low-frequency oscillator output.

Timers 0 and 1 may be clocked by one of five sources, determined by the Timer Mode Select bits (T1M–T0M) and the Clock Scale bits (SCA1–SCA0). The Clock Scale bits define a pre-scaled clock from which Timer 0 and/or Timer 1 may be clocked.

Timer 0/1 may then be configured to use this pre-scaled clock signal or the system clock. Timer 2 and Timer 3 may be clocked by the system clock, the system clock divided by 12, or the external clock divided by 8.

Timer 0 and Timer 1 may also be operated as counters. When functioning as a counter, a counter/timer register is incremented on each high-to-low transition at the selected input pin (T0 or T1). Events with a frequency of up to one-fourth the system clock frequency can be counted. The input signal need not be periodic, but it must be held at a given level for at least two full system clock cycles to ensure the level is properly sampled.

**Table 18.1. Timer Modes**

Timer 0 and Timer 1 Modes	Timer 2 Modes	Timer 3 Modes
13-bit counter/timer	16-bit timer with auto-reload	16-bit timer with auto-reload
16-bit counter/timer	Two 8-bit timers with auto-reload	Two 8-bit timers with auto-reload
8-bit counter/timer with auto-reload	Input pin capture	Low-frequency oscillator capture
Two 8-bit counter/timers (Timer 0 only)		

### 18.2 Features

Timer 0 and Timer 1 include the following features:

- Standard 8051 timers, supporting backwards-compatibility with firmware and hardware.
- Clock sources include SYSCLK, SYSCLK divided by 12, 4, or 48, the External Clock divided by 8, or an external pin.
- 8-bit auto-reload counter/timer mode
- 13-bit counter/timer mode
- 16-bit counter/timer mode
- Dual 8-bit counter/timer mode (Timer 0)

Timer 2 and Timer 3 are 16-bit timers including the following features:

- Clock sources include SYSCLK, SYSCLK divided by 12, or the External Clock divided by 8.
- 16-bit auto-reload timer mode
- Dual 8-bit auto-reload timer mode
- External pin capture (Timer 2)
- LFOSC0 capture (Timer 3)

## 18.3 Functional Description

### 18.3.1 System Connections

All four timers are capable of clocking other peripherals and triggering events in the system. The individual peripherals select which timer to use for their respective functions. Note that the Timer 2 and Timer 3 high overflows apply to the full timer when operating in 16-bit mode or the high-byte timer when operating in 8-bit split mode.

**Table 18.2. Timer Peripheral Clocking / Event Triggering**

Function	T0 Overflow	T1 Overflow	T2 High Overflow	T2 Low Overflow	T3 High Overflow	T3 Low Overflow
UART0 Baud Rate		Yes				
SMBus 0 Clock Rate (Master)	Yes	Yes	Yes	Yes		
SMBus 0 SCL Low Timeout					Yes	
PCA0 Clock	Yes					
ADC0 Conversion Start	Yes		Yes <sup>1</sup>	Yes <sup>1</sup>	Yes <sup>1</sup>	Yes <sup>1</sup>

**Notes:**

1. The high-side overflow is used when the timer is in 16-bit mode. The low-side overflow is used in 8-bit mode.

### 18.3.2 Timer 0 and Timer 1

Timer 0 and Timer 1 are each implemented as a 16-bit register accessed as two separate bytes: a low byte (TL0 or TL1) and a high byte (TH0 or TH1). The Counter/Timer Control register (TCON) is used to enable Timer 0 and Timer 1 as well as indicate status. Timer 0 interrupts can be enabled by setting the ET0 bit in the IE register. Timer 1 interrupts can be enabled by setting the ET1 bit in the IE register. Both counter/timers operate in one of four primary modes selected by setting the Mode Select bits T1M1–T0M0 in the Counter/Timer Mode register (TMOD). Each timer can be configured independently for the supported operating modes.

### 18.3.2.1 Operational Modes

#### Mode 0: 13-bit Counter/Timer

Timer 0 and Timer 1 operate as 13-bit counter/timers in Mode 0. The following describes the configuration and operation of Timer 0. However, both timers operate identically, and Timer 1 is configured in the same manner as described for Timer 0.

The TH0 register holds the eight MSBs of the 13-bit counter/timer. TL0 holds the five LSBs in bit positions TL0.4–TL0.0. The three upper bits of TL0 (TL0.7–TL0.5) are indeterminate and should be masked out or ignored when reading. As the 13-bit timer register increments and overflows from 0x1FFF (all ones) to 0x0000, the timer overflow flag TFO in TCON is set and an interrupt occurs if Timer 0 interrupts are enabled. The overflow rate for Timer 0 in 13-bit mode is:

$$F_{\text{TIMER0}} = \frac{F_{\text{Input Clock}}}{2^{13} - \text{TH0:TL0}} = \frac{F_{\text{Input Clock}}}{8192 - \text{TH0:TL0}}$$

The CT0 bit in the TMOD register selects the counter/timer's clock source. When CT0 is set to logic 1, high-to-low transitions at the selected Timer 0 input pin (T0) increment the timer register. Events with a frequency of up to one-fourth the system clock frequency can be counted. The input signal need not be periodic, but it must be held at a given level for at least two full system clock cycles to ensure the level is properly sampled. Clearing CT selects the clock defined by the T0M bit in register CKCON0. When T0M is set, Timer 0 is clocked by the system clock. When T0M is cleared, Timer 0 is clocked by the source selected by the Clock Scale bits in CKCON0.

Setting the TR0 bit enables the timer when either GATE0 in the TMOD register is logic 0 or based on the input signal INT0. The IN0PL bit setting in IT01CF changes which state of INT0 input starts the timer counting. Setting GATE0 to 1 allows the timer to be controlled by the external input signal INT0, facilitating pulse width measurements.

**Table 18.3. Timer 0 Run Control Options**

TR0	GATE0	INT0	IN0PL	Counter/Timer
0	X	X	X	Disabled
1	0	X	X	Enabled
1	1	0	0	Disabled
1	1	0	1	Enabled
1	1	1	0	Enabled
1	1	1	1	Disabled

**Note:**  
1. X = Don't Care

Setting TR0 does not force the timer to reset. The timer registers should be loaded with the desired initial value before the timer is enabled.

TL1 and TH1 form the 13-bit register for Timer 1 in the same manner as described above for TL0 and TH0. Timer 1 is configured and controlled using the relevant TCON and TMOD bits just as with Timer 0. The input signal INT1 is used with Timer 1, and IN1PL in register IT01CF determines the INT1 state that starts Timer 1 counting.

Figure 18.1. T0 Mode 0 Block Diagram

**Mode 1: 16-bit Counter/Timer**

Mode 1 operation is the same as Mode 0, except that the counter/timer registers use all 16 bits. The counter/timers are enabled and configured in Mode 1 in the same manner as for Mode 0. The overflow rate for Timer 0 in 16-bit mode is:

$$F_{\text{TIMER0}} = \frac{F_{\text{Input Clock}}}{2^{16} - \text{TH0:TL0}} = \frac{F_{\text{Input Clock}}}{65536 - \text{TH0:TL0}}$$

### Mode 2: 8-bit Counter/Timer with Auto-Reload

Mode 2 configures Timer 0 and Timer 1 to operate as 8-bit counter/timers with automatic reload of the start value. TL0 holds the count and TH0 holds the reload value. When the counter in TL0 overflows from all ones to 0x00, the timer overflow flag TF0 in the TCON register is set and the counter in TL0 is reloaded from TH0. If Timer 0 interrupts are enabled, an interrupt will occur when the TF0 flag is set. The reload value in TH0 is not changed. TL0 must be initialized to the desired value before enabling the timer for the first count to be correct. When in Mode 2, Timer 1 operates identically to Timer 0.

The overflow rate for Timer 0 in 8-bit auto-reload mode is:

$$F_{\text{TIMER0}} = \frac{F_{\text{Input Clock}}}{2^8 - \text{TH0}} = \frac{F_{\text{Input Clock}}}{256 - \text{TH0}}$$

Both counter/timers are enabled and configured in Mode 2 in the same manner as Mode 0. Setting the TR0 bit enables the timer when either GATE0 in the TMOD register is logic 0 or when the input signal INTO is active as defined by bit IN0PL in register IT01CF.

Figure 18.2. T0 Mode 2 Block Diagram

### Mode 3: Two 8-bit Counter/Timers (Timer 0 Only)

In Mode 3, Timer 0 is configured as two separate 8-bit counter/timers held in TL0 and TH0. The counter/timer in TL0 is controlled using the Timer 0 control/status bits in TCON and TMOD: TR0, CT0, GATE0, and TF0. TL0 can use either the system clock or an external input signal as its timebase. The TH0 register is restricted to a timer function sourced by the system clock or prescaled clock. TH0 is enabled using the Timer 1 run control bit TR1. TH0 sets the Timer 1 overflow flag TF1 on overflow and thus controls the Timer 1 interrupt.

The overflow rate for Timer 0 Low in 8-bit mode is:

$$F_{\text{TIMER0}} = \frac{F_{\text{Input Clock}}}{2^8 - \text{TL0}} = \frac{F_{\text{Input Clock}}}{256 - \text{TL0}}$$

The overflow rate for Timer 0 High in 8-bit mode is:

$$F_{\text{TIMER0}} = \frac{F_{\text{Input Clock}}}{2^8 - \text{TH0}} = \frac{F_{\text{Input Clock}}}{256 - \text{TH0}}$$

Timer 1 is inactive in Mode 3. When Timer 0 is operating in Mode 3, Timer 1 can be operated in Modes 0, 1 or 2, but cannot be clocked by external signals nor set the TF1 flag and generate an interrupt. However, the Timer 1 overflow can be used to generate baud rates for the SMBus and/or UART, and/or initiate ADC conversions. While Timer 0 is operating in Mode 3, Timer 1 run control is handled through its mode settings. To run Timer 1 while Timer 0 is in Mode 3, set the Timer 1 Mode as 0, 1, or 2. To disable Timer 1, configure it for Mode 3.

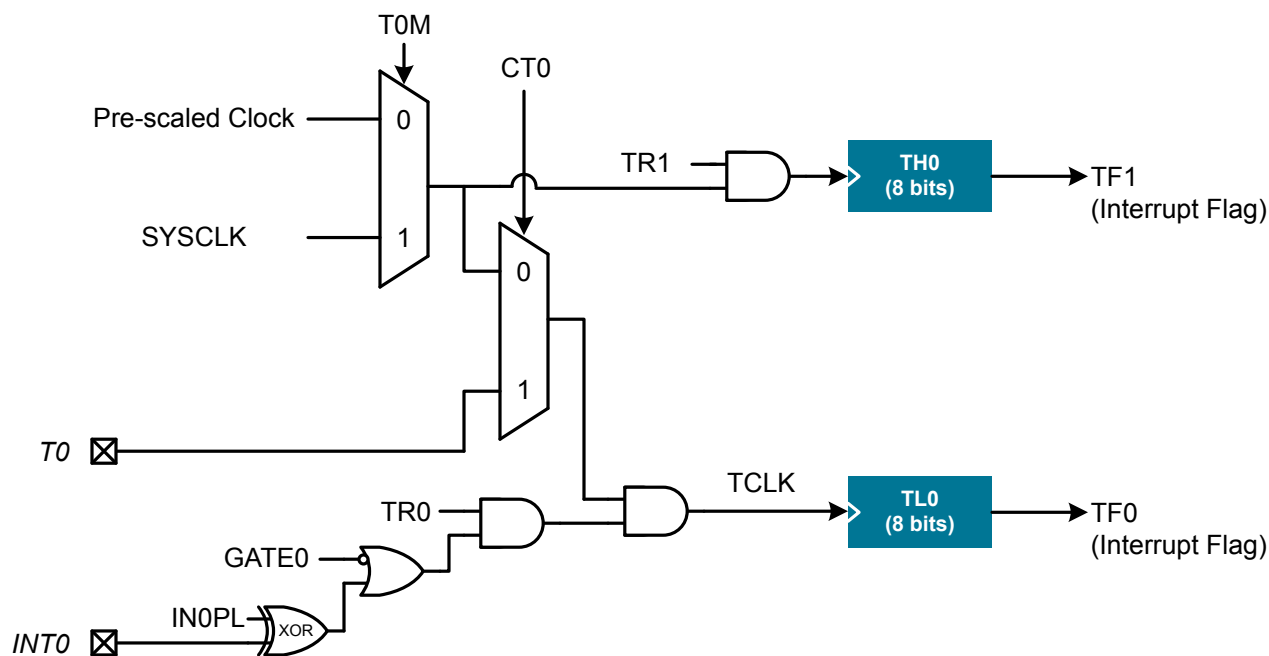

Figure 18.3. T0 Mode 3 Block Diagram

### 18.3.3 Timer 2 and Timer 3

Timer 2 and Timer 3 are functionally equivalent, with the only differences being the top-level connections to other parts of the system.

The timers are 16 bits wide, formed by two 8-bit SFRs: TMRnL (low byte) and TMRnH (high byte). Each timer may operate in 16-bit auto-reload mode, dual 8-bit auto-reload (split) mode, or capture mode.

## Clock Selection

Clocking for each timer is configured using the TnXCLK bit field and the TnML and TnMH bits. Both timers may be clocked by the system clock, the system clock divided by 12, or the external clock source divided by 8 (synchronized with SYSCLK).

$$F_{\text{SYSCLK}} > F_{\text{EXTCLK}} \times \frac{6}{7}$$

When operating in one of the 16-bit modes, the low-side timer clock is used to clock the entire 16-bit timer.

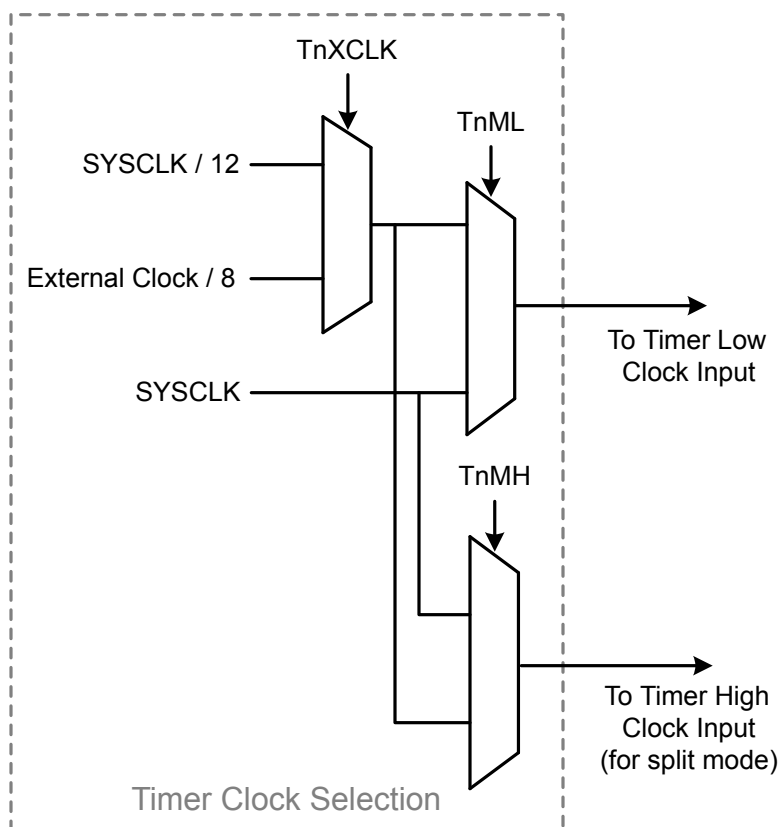

Figure 18.4. Timer 2 and 3 Clock Source Selection

## Capture Sources

Capture mode allows an external input (Timer 2) or the low-frequency oscillator clock (Timer 3) to be measured against the selected clock source. The timer 2 capture input (T2) is routed to an external pin using the crossbar.

Figure 18.5. Timer 2 and 3 Capture Sources

### 18.3.3.1 16-bit Timer with Auto-Reload

When TnSPLIT is zero, the timer operates as a 16-bit timer with auto-reload. In this mode, the selected clock source increments the timer on every clock. As the 16-bit timer register increments and overflows from 0xFFFF to 0x0000, the 16-bit value in the timer reload registers (TMRnRLH and TMRnRLL) is loaded into the main timer count register, and the High Byte Overflow Flag (TFnH) is set. If the timer interrupts are enabled, an interrupt is generated on each timer overflow. Additionally, if the timer interrupts are enabled and the TFnLEN bit is set, an interrupt is generated each time the lower 8 bits (TMRnL) overflow from 0xFF to 0x00.

The overflow rate of the timer in split 16-bit auto-reload mode is:

$$F_{\text{TIMERn}} = \frac{F_{\text{Input Clock}}}{2^{16} - \text{TMRnRLH:TMRnRLL}} = \frac{F_{\text{Input Clock}}}{65536 - \text{TMRnRLH:TMRnRLL}}$$

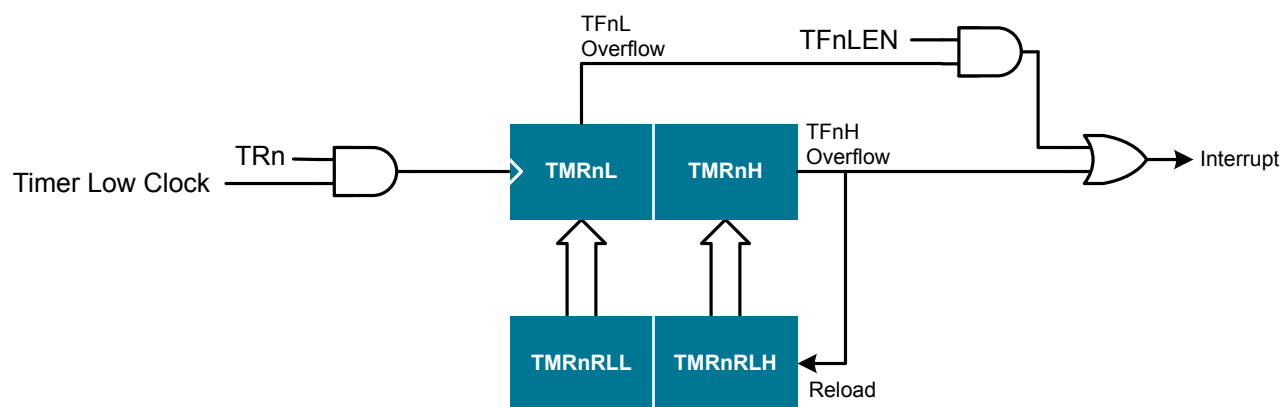

Figure 18.6. 16-Bit Mode Block Diagram

### 18.3.3.2 8-bit Timers with Auto-Reload (Split Mode)

When TnSPLIT is set, the timer operates as two 8-bit timers (TMRnH and TMRnL). Both 8-bit timers operate in auto-reload mode. TMRnRLL holds the reload value for TMRnL; TMRnRLH holds the reload value for TMRnH. The TRn bit in TMRnCN handles the run control for TMRnH. TMRnL is always running when configured for 8-bit auto-reload mode. As shown in the clock source selection tree, the two halves of the timer may be clocked from SYSCLK or by the source selected by the TnXCLK bits.

The overflow rate of the low timer in split 8-bit auto-reload mode is:

$$F_{\text{TIMERn Low}} = \frac{F_{\text{Input Clock}}}{2^8 - \text{TMRnRLL}} = \frac{F_{\text{Input Clock}}}{256 - \text{TMRnRLL}}$$

The overflow rate of the high timer in split 8-bit auto-reload mode is:

$$F_{\text{TIMERn High}} = \frac{F_{\text{Input Clock}}}{2^8 - \text{TMRnRLH}} = \frac{F_{\text{Input Clock}}}{256 - \text{TMRnRLH}}$$

The TFnH bit is set when TMRnH overflows from 0xFF to 0x00; the TFnL bit is set when TMRnL overflows from 0xFF to 0x00. When timer interrupts are enabled, an interrupt is generated each time TMRnH overflows. If timer interrupts are enabled and TFnLEN is set, an interrupt is generated each time either TMRnL or TMRnH overflows. When TFnLEN is enabled, software must check the TFnH and TFnL flags to determine the source of the timer interrupt. The TFnH and TFnL interrupt flags are not cleared by hardware and must be manually cleared by software.

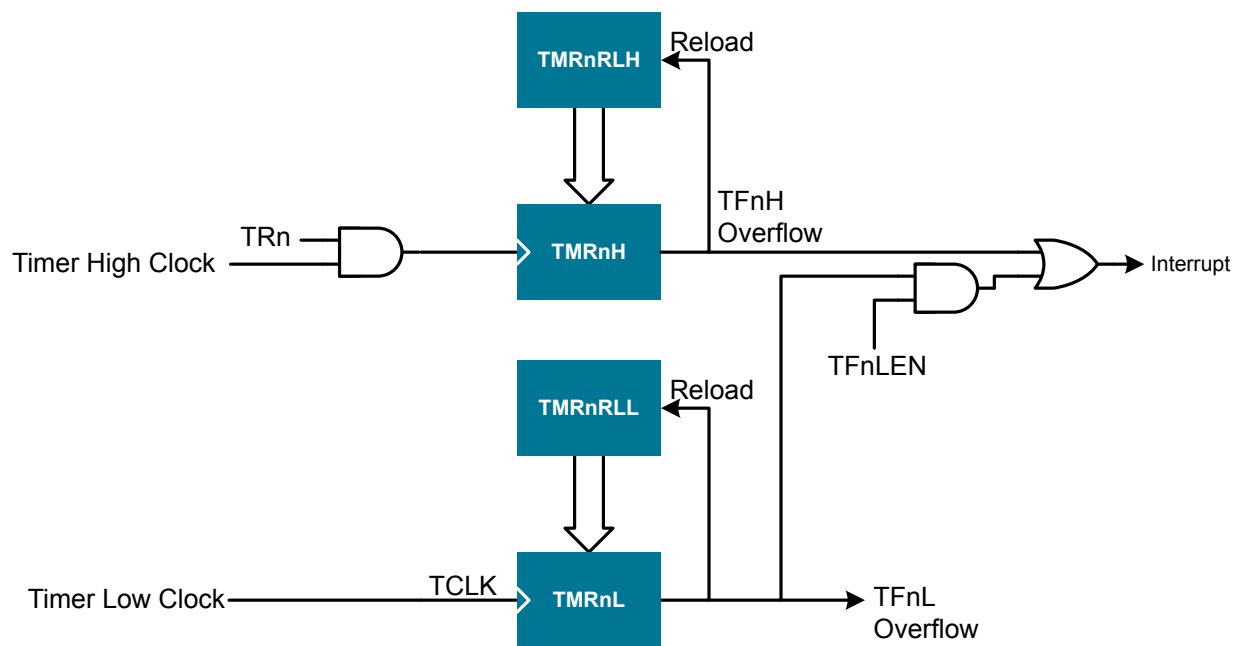

Figure 18.7. 8-Bit Split Mode Block Diagram

### 18.3.3.3 Capture Mode

Capture mode allows a system event to be measured against the selected clock source. When used in capture mode, the timer clocks normally from the selected clock source through the entire range of 16-bit values from 0x0000 to 0xFFFF.

Setting TFnCEN to 1 enables capture mode. In this mode, TnSPLIT should be set to 0, as the full 16-bit timer is used. Upon a falling edge of the input capture signal, the contents of the timer register (TMRnH:TMRnL) are loaded into the reload registers (TMRnRLH:TMRnRLL) and the TFnH flag is set. By recording the difference between two successive timer capture values, the period of the captured signal can be determined with respect to the selected timer clock.

Figure 18.8. Capture Mode Block Diagram

## 19. Universal Asynchronous Receiver/Transmitter 0 (UART0)

### 19.1 Introduction

UART0 is an asynchronous, full duplex serial port offering modes 1 and 3 of the standard 8051 UART. Enhanced baud rate support allows a wide range of clock sources to generate standard baud rates. Received data buffering allows UART0 to start reception of a second incoming data byte before software has finished reading the previous data byte.

UART0 has two associated SFRs: Serial Control Register 0 (SCON0) and Serial Data Buffer 0 (SBUF0). The single SBUF0 location provides access to both transmit and receive registers.

**Note:** Writes to SBUF0 always access the transmit register. Reads of SBUF0 always access the buffered receive register; it is not possible to read data from the transmit register.

With UART0 interrupts enabled, an interrupt is generated each time a transmit is completed (TI is set in SCON0), or a data byte has been received (RI is set in SCON0). The UART0 interrupt flags are not cleared by hardware when the CPU vectors to the interrupt service routine. They must be cleared manually by software, allowing software to determine the cause of the UART0 interrupt (transmit complete or receive complete).

Figure 19.1. UART0 Block Diagram

### 19.2 Features

The UART uses two signals (TX and RX) and a predetermined fixed baud rate to provide asynchronous communications with other devices.

The UART module provides the following features:

- Asynchronous transmissions and receptions
- Baud rates up to  $\text{SYSCLK}/2$  (transmit) or  $\text{SYSCLK}/8$  (receive)
- 8- or 9-bit data
- Automatic start and stop generation

## 19.3 Functional Description

### 19.3.1 Baud Rate Generation

The UART0 baud rate is generated by Timer 1 in 8-bit auto-reload mode. The TX clock is generated by TL1; the RX clock is generated by a copy of TL1, which is not user-accessible. Both TX and RX timer overflows are divided by two to generate the TX and RX baud rates. The RX timer runs when Timer 1 is enabled and uses the same reload value (TH1). However, an RX timer reload is forced when a START condition is detected on the RX pin. This allows a receive to begin any time a START is detected, independent of the TX timer state.

Figure 19.2. UART0 Baud Rate Logic Block Diagram

Timer 1 should be configured for 8-bit auto-reload mode (mode 2). The Timer 1 reload value and prescaler should be set so that overflows occur at twice the desired UART0 baud rate. The UART0 baud rate is half of the Timer 1 overflow rate. Configuring the Timer 1 overflow rate is discussed in the timer sections.

### 19.3.2 Data Format

UART0 has two options for data formatting. All data transfers begin with a start bit (logic low), followed by the data (sent LSB-first), and end with a stop bit (logic high). The data length of the UART0 module is normally 8 bits. An extra 9th bit may be added to the MSB of data field for use in multi-processor communications or for implementing parity checks on the data. The S0MODE bit in the SCON register selects between 8 or 9-bit data transfers.

Figure 19.3. 8-Bit Data Transfer

Figure 19.4. 9-Bit Data Transfer

### 19.3.3 Data Transfer

UART0 provides standard asynchronous, full duplex communication. All data sent or received goes through the SBUF0 register and (in 9-bit mode) the RB8 bit in the SCON0 register.

#### Transmitting Data

Data transmission is initiated when software writes a data byte to the SBUF0 register. If 9-bit mode is used, software should set up the desired 9th bit in TB8 prior to writing SBUF0. Data is transmitted LSB first from the TX pin. The TI flag in SCON0 is set at the end of the transmission (at the beginning of the stop-bit time). If TI interrupts are enabled, TI will trigger an interrupt.

#### Receiving Data

To enable data reception, firmware should write the REN bit to 1. Data reception begins when a start condition is recognized on the RX pin. Data will be received at the selected baud rate through the end of the data phase. Data will be transferred into the receive buffer under the following conditions:

- There is room in the receive buffer for the data.
- MCE is set to 1 and the stop bit is also 1 (8-bit mode).
- MCE is set to 1 and the 9th bit is also 1 (9-bit mode).
- MCE is 0 (stop or 9th bit will be ignored).

In the event that there is not room in the receive buffer for the data, the most recently received data will be lost. The RI flag will be set any time that valid data has been pushed into the receive buffer. If RI interrupts are enabled, RI will trigger an interrupt. Firmware may read the 8 LSBs of received data by reading the SBUF0 register. The RB8 bit in SCON0 will represent the 9th received bit (in 9-bit mode) or the stop bit (in 8-bit mode), and should be read prior to reading SBUF0.

### 19.3.4 Multiprocessor Communications

9-Bit UART mode supports multiprocessor communication between a master processor and one or more slave processors by special use of the ninth data bit. When a master processor wants to transmit to one or more slaves, it first sends an address byte to select the target(s). An address byte differs from a data byte in that its ninth bit is logic 1; in a data byte, the ninth bit is always set to logic 0.

Setting the MCE bit of a slave processor configures its UART such that when a stop bit is received, the UART will generate an interrupt only if the ninth bit is logic 1 (RB8 = 1) signifying an address byte has been received. In the UART interrupt handler, software will compare the received address with the slave's own assigned 8-bit address. If the addresses match, the slave will clear its MCE bit to enable interrupts on the reception of the following data byte(s). Slaves that weren't addressed leave their MCE bits set and do not generate interrupts on the reception of the following data bytes, thereby ignoring the data. Once the entire message is received, the addressed slave resets its MCE bit to ignore all transmissions until it receives the next address byte.

Multiple addresses can be assigned to a single slave and/or a single address can be assigned to multiple slaves, thereby enabling "broadcast" transmissions to more than one slave simultaneously. The master processor can be configured to receive all transmissions or a protocol can be implemented such that the master/slave role is temporarily reversed to enable half-duplex transmission between the original master and slave(s).

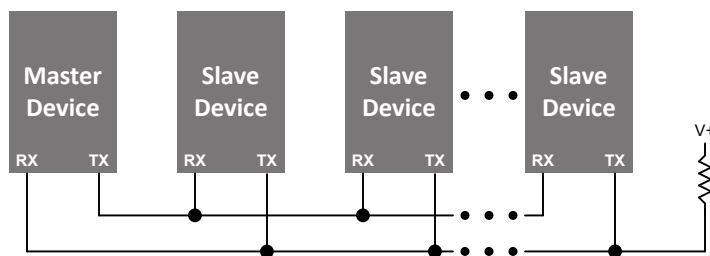

Figure 19.5. Multi-Processor Mode Interconnect Diagram

## 19.4 UART0 Control Registers

### 19.4.1 SCON0: UART0 Serial Port Control

### 19.4.2 SBUF0: UART0 Serial Port Data Buffer

Bit	7	6	5	4	3	2	1	0
Name	SBUF0							
Access	RW							
Reset	0x00							
SFR Address: 0x99								

Bit	Name	Reset	Access	Description
7:0	SBUF0	0x00	RW	<p><b>Serial Data Buffer.</b></p> <p>This SFR accesses two registers: a transmit shift register and a receive latch register. When data is written to SBUF0, it goes to the transmit shift register and is held for serial transmission. Writing a byte to SBUF0 initiates the transmission. A read of SBUF0 returns the contents of the receive latch.</p>

## 20. Watchdog Timer (WDT0)

### 20.1 Introduction

The device includes a programmable watchdog timer (WDT) running off the low-frequency oscillator. A WDT overflow forces the MCU into the reset state. To prevent the reset, the WDT must be restarted by application software before overflow. If the system experiences a software or hardware malfunction preventing the software from restarting the WDT, the WDT overflows and causes a reset.

Following a reset, the WDT is automatically enabled and running with the default maximum time interval. If needed, the WDT can be disabled by system software or locked on to prevent accidental disabling. Once locked, the WDT cannot be disabled until the next system reset. The state of the RSTb pin is unaffected by this reset.

The WDT consists of an internal timer running from the low-frequency oscillator. The timer measures the period between specific writes to its control register. If this period exceeds the programmed limit, a WDT reset is generated. The WDT can be enabled and disabled as needed in software, or can be permanently enabled if desired. When the WDT is active, the low-frequency oscillator is forced on. All watchdog features are controlled via the Watchdog Timer Control Register (WDTCN).

Figure 20.1. Watchdog Timer Block Diagram

### 20.2 Features

The watchdog timer includes a 16-bit timer with a programmable reset period. The registers are protected from inadvertent access by an independent lock and key interface.

The Watchdog Timer has the following features:

- Programmable timeout interval
- Runs from the low-frequency oscillator
- Lock-out feature to prevent any modification until a system reset

### 20.3 Using the Watchdog Timer

#### Enabling/Resetting the WDT

The watchdog timer is both enabled and reset by writing 0xA5 to the WDTCN register. The user's application software should include periodic writes of 0xA5 to WDTCN as needed to prevent a watchdog timer overflow. The WDT is enabled and reset as a result of any system reset.

## Disabling the WDT

Writing 0xDE followed by 0xAD to the WDTCN register disables the WDT. The following code segment illustrates disabling the WDT:

```
CLR EA      ; disable all interrupts
MOV WDTCN,#0DEh ; disable software watchdog timer
MOV WDTCN,#0ADh
SETB EA    ; re-enable interrupts
```

The writes of 0xDE and 0xAD must occur within 4 clock cycles of each other, or the disable operation is ignored. Interrupts should be disabled during this procedure to avoid delay between the two writes.

## Disabling the WDT Lockout

Writing 0xFF to WDTCN locks out the disable feature. Once locked out, the disable operation is ignored until the next system reset. Writing 0xFF does not enable or reset the watchdog timer. Applications always intending to use the watchdog should write 0xFF to WDTCN in the initialization code.

## Setting the WDT Interval

WDTCN.[2:0] controls the watchdog timeout interval. The interval is given by the following equation, where  $T_{LFOSC}$  is the low-frequency oscillator clock period:

$$T_{LFOSC} \times 4^{(WDTCN[2:0]+3)}$$

This provides a nominal interval range of 0.8 ms to 13.1 s when LFOSC0 is configured to run at 80 kHz. WDTCN.7 must be logic 0 when setting this interval. Reading WDTCN returns the programmed interval. WDTCN.[2:0] reads 111b after a system reset.

## 20.4 WDT0 Control Registers

### 20.4.1 WDTCN: Watchdog Timer Control

Bit	7	6	5	4	3	2	1	0
Name	WDTCN							
Access	RW							
Reset	0x17							
SFR Address: 0x97								

Bit	Name	Reset	Access	Description
7:0	WDTCN	0x17	RW	<b>WDT Control.</b> The WDT control field has different behavior for reads and writes. Read: When reading the WDTCN register, the lower three bits (WDTCN[2:0]) indicate the current timeout interval. Bit WDTCN.4 indicates whether the WDT is active (logic 1) or inactive (logic 0). Write: Writing the WDTCN register can set the timeout interval, enable the WDT, disable the WDT, reset the WDT, or lock the WDT to prevent disabling. Writing to WDTCN with the MSB (WDTCN.7) cleared to 0 will set the timeout interval to the value in bits WDTCN[2:0]. Writing 0xA5 both enables and reloads the WDT. Writing 0xDE followed within 4 system clocks by 0xAD disables the WDT. Writing 0xFF locks out the disable feature until the next device reset.

## 21. C2 Debug and Programming Interface

### 21.1 Introduction

The device includes an on-chip Silicon Labs 2-Wire (C2) debug interface that allows flash programming and in-system debugging with the production part installed in the end application. The C2 interface uses a clock signal (C2CK) and a bi-directional C2 data signal (C2D) to transfer information between the device and a host system. Details on the C2 protocol can be found in the C2 Interface Specification.

### 21.2 Features

The C2 interface provides the following features:

- In-system device programming and debugging.
- Non-intrusive - no firmware or hardware peripheral resources required.
- Allows inspection and modification of all memory spaces and registers.
- Provides hardware breakpoints and single-step capabilities.
- Can be locked via flash security mechanism to prevent unwanted access.

### 21.3 Pin Sharing

The C2 protocol allows the C2 pins to be shared with user functions so that in-system debugging and flash programming may be performed. C2CK is shared with the RSTb pin, while the C2D signal is shared with a port I/O pin. This is possible because C2 communication is typically performed when the device is in the halt state, where all on-chip peripherals and user software are stalled. In this halted state, the C2 interface can safely "borrow" the C2CK and C2D pins. In most applications, external resistors are required to isolate C2 interface traffic from the user application.

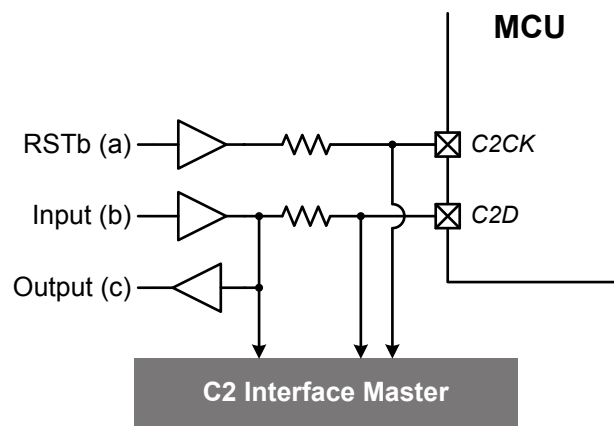

Figure 21.1. Typical C2 Pin Sharing

The configuration above assumes the following:

- The user input (b) cannot change state while the target device is halted.
- The RSTb pin on the target device is used as an input only.

Additional resistors may be necessary depending on the specific application.

## 21.4 C2 Interface Registers

### 21.4.1 C2ADD: C2 Address

Bit	7	6	5	4	3	2	1	0
Name	C2ADD							
Access	RW							
Reset	0x00							
This register is part of the C2 protocol.								

Bit	Name	Reset	Access	Description
7:0	C2ADD	0x00	RW	<b>C2 Address.</b>  The C2ADD register is accessed via the C2 interface. The value written to C2ADD selects the target data register for C2 Data Read and Data Write commands.  0x00: C2DEVID 0x01: C2REVID 0x02: C2FPCTL 0xB4: C2FPDAT

### 21.4.2 C2DEVID: C2 Device ID

Bit	7	6	5	4	3	2	1	0
Name	C2DEVID							
Access	R							
Reset	0x30							
C2 Address: 0x00								

Bit	Name	Reset	Access	Description
7:0	C2DEVID	0x30	R	<b>Device ID.</b>  This read-only register returns the 8-bit device ID.

### 21.4.3 C2REVID: C2 Revision ID

Bit	7	6	5	4	3	2	1	0
Name	C2REVID							
Access	R							
Reset	Varies							
C2 Address: 0x01								

Bit	Name	Reset	Access	Description
7:0	C2REVID	Varies	R	<b>Revision ID.</b>  This read-only register returns the 8-bit revision ID. For example: 0x02 = Revision A.

#### 21.4.4 C2FPCTL: C2 Flash Programming Control

Bit	7	6	5	4	3	2	1	0
Name	C2FPCTL							
Access	RW							
Reset	0x00							
C2 Address: 0x02								

Bit	Name	Reset	Access	Description
7:0	C2FPCTL	0x00	RW	<b>Flash Programming Control Register.</b>  This register is used to enable flash programming via the C2 interface. To enable C2 flash programming, the following codes must be written in order: 0x02, 0x01. Note that once C2 flash programming is enabled, a system reset must be issued to resume normal operation.

#### 21.4.5 C2FPDAT: C2 Flash Programming Data

Bit	7	6	5	4	3	2	1	0
Name	C2FPDAT							
Access	RW							
Reset	0x00							
C2 Address: 0xB4								

Bit	Name	Reset	Access	Description
7:0	C2FPDAT	0x00	RW	<b>C2 Flash Programming Data Register.</b>  This register is used to pass flash commands, addresses, and data during C2 flash accesses. Valid commands are listed below.  0x03: Device Erase 0x06: Flash Block Read 0x07: Flash Block Write 0x08: Flash Page Erase

### Disclaimer

Silicon Laboratories intends to provide customers with the latest, accurate, and in-depth documentation of all peripherals and modules available for system and software implementers using or intending to use the Silicon Laboratories products. Characterization data, available modules and peripherals, memory sizes and memory addresses refer to each specific device, and "Typical" parameters provided can and do vary in different applications. Application examples described herein are for illustrative purposes only. Silicon Laboratories reserves the right to make changes without further notice and limitation to product information, specifications, and descriptions herein, and does not give warranties as to the accuracy or completeness of the included information. Silicon Laboratories shall have no liability for the consequences of use of the information supplied herein. This document does not imply or express copyright licenses granted hereunder to design or fabricate any integrated circuits. The products must not be used within any Life Support System without the specific written consent of Silicon Laboratories. A "Life Support System" is any product or system intended to support or sustain life and/or health, which, if it fails, can be reasonably expected to result in significant personal injury or death. Silicon Laboratories products are generally not intended for military applications. Silicon Laboratories products shall under no circumstances be used in weapons of mass destruction including (but not limited to) nuclear, biological or chemical weapons, or missiles capable of delivering such weapons.
